TOMATOES require frequent pruning. Cut away all lateral growth, and concentrate the energy of the plant on perfecting the early-set fruit; late blooms only rob the fruits that have any chance of ripening.

J. GROOM, *Correspondent.*

BEANS—Sorra and French Beans for winter. —French Beans may be preserved in an earthenware pan, mixed with salt, kept in a cool cellar. I should think good might be kept on the silo principle—i.e., cut when dry, and in a large pan, with a heavy weight upon it to keep out all the air, to prevent fermentation.

Geum miniatum.—One of the best of hardy perennials is this Geum, which produces a wealth of flowers from quite early in the summer until cut off by frosts. It reminds one of *G. oococcinum*, and is a plant of great vigour, with bold foliage, and bears large flowers of an orange-scarlet colour. A clump of it is very effective, and one great charm is its long continuance in bloom. It is easily propagated, and is in all respects a good garden plant.—V. C.

Tropæolum Vesuvium.—This variety of Tropæolum or Nasturtium is worth a good note. It is conspicuous for neatness of habit, the growth very compact, dense, and the flowers produced just above the wealth of dark-green leaves, which produce a fine contrast to the intense scarlet flowers. A mass of it is most brilliant, a perfect surface of rich colour. Such a variety is of value for effect in beds, and is a distinct improvement upon the usual type of Tropæolum, which produces plenty of leaves but not sufficient flowers, and these are hidden beneath the foliage.—C. T.

Perennial Sunflowers.—Amongst the finest of late summer and autumn flowers are the Helianthines of perennial kinds. One of the most important is *H. luteiflora*, which has flowers of a rich yellow colour, large, produced freely, the disc also purple. It is late in bloom, and valuable on that account. The varieties of the common *H. multiflorus* are well known, and a fine variety is *multiflorus*, which has large, boldly-shaped blooms, the growth of the plant very robust. A good mass of it is effective at this season of the year, but in growing the perennial Sunflowers it is necessary not to plant them too freely, as a surfeit of yellow is produced. This is objectionable. Free, graceful, and obnoxious varieties are those of the type of *H. orgyalis*, which are useful to plant amongst shrubs, over which they throw their stems, bearing a free display of yellow flowers. This kind will grow almost anywhere, in the poorest soils and positions, even in the shade. The stems rise over 5 feet in height, and the plants grow in ordinary soils, becoming almost weeds in time. *H. rigidus*, better known perhaps as *Herpalium rigidum*, is a splendid perennial, free, showy, and growing about 3 feet in height. Like all of this class, it makes a very quick growth, and requires ample space to spread.—V. C.

4282. — **Destroying wireworms**.—Newly broken up pasture is usually full of wireworm, but for, say the first two years, a dressing of salt at the rate of 8 cwt. or 8 owt. to the acre will be beneficial. The dressings should be applied in cloudy and showery weather, and on fine days well stir the surface of the soil. There is nothing like high cultivation for wireworms, and constant hoeing also is a good remedy. When plants are affected and it is impossible to give dressings of gas-lime or soot, Potato slicings or Carrots inserted in the ground will prove good traps. A very common plan is to put down—first, a crop of Potatoes, the thorough stirring up of the soil necessary for them and the crop itself proving good traps.—C. T.

Chrysanthemum-buds.—In the first place, I should say "W. Simpson" cannot have his plants correctly named. I never heard of a bloom of Chrysa reaching the dimensions of an ordinary saucer. However, the month of July is too early to "take" buds of any varieties of Chrysanthemums belonging to the incurved section, and but few exceptions among the Japanese. If buds formed in July like those received they should be nipped out and wait for the next, which would form about the middle of August. Any buds that form after these lines are in print should be retained. Blooms from buds formed earlier are rough.—E. M.

4294. — **A tenant's fixture greenhouse**.—Your idea of putting down a row of bricks to prevent damp is good, and I believe quite legal for tenant's fixture; but if the house is to stand in an exposed position, I do not think your plan is substantial enough. A similar structure has just been erected under my superintendance, and in the place of bricks I have used old railway baulks for the wood-work to rest upon, and to which the latter is fixed by screws.—J. C. C.

New Zealand Flax.—This handsome plant flowered and ripened its seed three years ago outside here. It was the sown by the victors in the grounds at Belmont, Torquay, Devonshire, in 1890.

FRUIT.

AUGUST PEARS.

AMONGST the most useful of the August varieties of Pear is

CITRON DES CARMES, of which an illustration is given. It is a well-known variety, ripe at the end of July and August, and a most delicious Pear. The fruit is very small, obovate in form, and with a smooth green skin, that assumes towards the ripening stage a yellowish tinge, while they are borne together in small clusters. The flavour is very sweet and agreeable, the flesh yellowish-white and juicy. This makes a handsome standard, and may also be grown as a pyramid.

DOYENNE D'ETE is another fine early variety sometimes called Summer Doyenne. The fruit, when eaten in the proper stage, is of delicious quality, but unless picked before fully ripe is very second rate. Like those of Citron des Carmes, the fruits are unfortunately of small size, the form roundish and neat, and the colour a fine yellow-green, which becomes of a clear yellow as the fruit attains maturity. It makes a good pyramid or standard, and bears well.

JARONELLE.—This is a popular early variety, the fruits of large size, with the skin of a yellowish hue, enlivened with a flush of reddish-brown on the sunny side. The flesh is sweet, melting, and juicy, and the flavour pleasant, with a faint trace of Musk. This tree does well as a standard, and it is a free grower, the branches being long and straggling. It will not succeed as a pyramid, but does well against a wall, and in a warm, sheltered position the fruits attain a large size. It requires root-pruning occasionally to check its vigorous growth. Where there is not space for Citron des Carmes and Doyenne d'Été this tree should certainly be cultivated, as it possesses splendid qualities, and a ripe, juicy Pear in August is a delicacy.

SOUVENIR DU CONGRES.—This handsome Pear ripens at the end of August, and though not so popular as Williams' Bon Chrétien, which it resembles, is a desirable variety.

WILLIAMS' BON CHRÉTIEN.—This is, perhaps, the best known of all varieties, and is largely grown in the orchards about London. It comes in late in August, and has a short season, though we find so-called "Williams" on the harrows long after the fruits of the real variety are over. A good many varieties go under the name of this famous Pear. The tree makes a good standard, pyramid, or espalier. The flavour is rich, melting, sweet, but rather objectionably musty. E.

4262.—Black Currant bushes.—If the trees had been well-syringed with Tobacco-water and soft-soap, prepared in the following manner, the green-fly would not have prevented the fruit swelling: Take 2 lb. Tobacco-paper, soak it thoroughly in hot water, and dissolve 3 lb. soft-soap, add sufficient warm water to make 40 gallons, and well wash the trees with it in the evening at a temperature of 80 degs. Early next morning thoroughly drench the trees with clean water. After this but little trouble will be experienced with aphides of any kind. Directly the leaves are off is the time to prune the trees. As Black Currants bear the best on young wood, this should be encouraged. Cut away any old branches that are crowding younger ones. Do not cut off the points of young shoots, but leave them their full length. If the trees do not make growth freely, fork some well-rotted manure in about the roots after pruning.—S. P.

—Prune Black Currants when the leaves fall. Leave as much young wood in as possible, and take a few of the old branches out occasionally to encourage young shoots to break out. Black Currants bear chiefly on the young wood, and very little shortening should be done. They require manure, and should be mulched in a season like the present.—E. H.

4271.—Manure for Vines.—I have no personal experience of graves as a manure for Vines, but I have known them recommended for Chrysanthemums, and if they are good for these plants they could be no other than beneficial to Vines. I should advise that a thin dressing be sprinkled on the surface, and afterwards lightly forking them, but not in such a manner as to injure the roots. I should not advise anyone though to buy graves as manure for

Vines. I much prefer Thomson's or Innes' properly-prepared manure for Vines, and from personal experience I know both to be good. Two dressings of either in a year is quite sufficient, one in the autumn or spring, when the borders are renovated on the surface, and again after the bunches are thinned. Animal manures are most efficacious stimulants for Vines, especially when growing in an isoid border. If the natural soil of the border is inclined to be sandy I prefer to use manure from the cow-sheds, if the reverse—heavy—I like horse-manure. Either kind should be in a half-rotted state, but not more decomposed than that, or the goodness will have left the manure. A mulch of 3 inches thick laid on the border directly the Vines are thinned acts in a beneficial manner. The goodness from the manure is washed down to the roots, and the surface of the border is kept cool and moist, thereby encouraging surface-roots to increase.—S. P.

4269.—An old Apple-tree.—Probably your plant is worn out, or else it has established its roots in a very poor or cold subsoil. You might remove some of the soil around it, and replace with a good compost, or give it a few thorough soakings of liquid-manure during the winter. The best plan of all would be to cut it down, and plant a healthy young tree in its place. This would fruit the second year, giving

cleansing the branches: Dissolve 5 lb. caustic soda (Greenbanks, 98 per cent.) and 5 lb. pearl-ash in hot water, add cold water enough to make 50 gallons. In dissolving the soda great care should be exercised, as it is dangerous if any of it touches the skin, and it boils up after the manner of quicklime when the water is poured on. Apply the mixture to the trees with a fine-roed syringe, thoroughly wetting every part any time after the leaves have fallen. Should any Moss not be killed by the first application give another towards the end of February; but if the work is thoroughly carried out a second washing will not be needed.—S. P.

4301.—Treatment of an Apple and Pear tree.—Not only are the trees making too much growth to give a full crop of fruit, consequent upon the too free use of liquid-manure, but I suspect the roots are too deep in the soil. They are too far away from the warming influence of the sun shining upon them, and especially if the Grass is growing close up to the stem of the trees. I should at once thin out the shoots to admit of light, air, and wind to the innermost parts of the trees. Cut away all surplus shoots—those not required for extending the area of the tree or filling up gaps in the branches of the tree, as it takes years to finally shape a tree in such a manner that the adding of a branch or shoot the shape is not improved.

Early Pear "Citron des Carmes."

large handsome Apples, and improving year by year.—P. U.

—If the variety is a choice one it may be well to set about renovating the tree; if not, chop it down and plant a young one in its place of an approved kind. If an early cooking variety is preferred, plant Lord Grosvenor; if a late sort, none is better than Lane's Prince Albert. Purchase a good tree. Do not begrudge a shilling or two extra; far better to buy a good article at first, and with good management a crop of fruit can be taken off in the second season after planting. The best way to set about renovating the old tree is to remove the top spit of soil 4 inches deep, and if roots are found there replace it with some half-rotten manure, wood ashes, decayed vegetable refuse, and road-grit. The first week in October is a good time to do this. If the weather during the following January or February is dry without being frosty, thoroughly soak the soil with liquid-manure. One hundred gallons would not be too much for a large tree. It is useless pouring it on the soil close around the stem of the tree only; the soil at least 15 feet away from the stem should receive its share, as that is where many of the small roots would be found, and these really are the feeders, not the long, fibreless roots. It is useless, however, to spend time in renovating the roots if the branches do not also receive attention. Most likely they are covered with Moss and Lichen in such a manner that the trees cannot be healthy with such a coating of this parasite. The following is a splendid recipe for

The current year's shoots might be cut to within 2 inches of their base, as the season is too far advanced for a second growth to be made. If it is not practicable to replant the trees entirely, I should advise that the turf be taken off for at least 4 feet away from the stem all around, afterwards root-pruning the trees; this is best done the last week in September. Cut a trench at the distance named from the stem of the tree, and as deep as roots are found. The severing of these will check the luxuriant growth the following year and induce fertility. Until a full crop of fruit is borne do not give stimulative food in any form; the trees have had too much of this.—S. P.

—If the trees are much crowded in their growth the wood will not ripen, and there will not be much fruit. Thin out a few small shoots to let in the air and sun shine. Possibly the roots may require checking; if so, open a trench 3 feet from stem on one side, and prune the roots, setting under the ball as much as possible to cut tap-roots. Do this work early in October.—E. H.

4304.—Treatment of Vines.—It is unwise both to allow the rods to travel too quickly up the roof and to allow them to bear too heavy a crop of fruit during their early stage of existence. What I mean by travelling too quickly up the roof is by allowing too great a length of cane to remain yearly at pruning-time. If too great a length is left the back eyes belonging to the growth of the year previous do not push into growth so freely as the eyes nearer to the point, consequent on the flow of sap reaching to the extreme end of the Vine. Vines properly managed should give full crops of Grapes yearly

for at least thirty years, and without much apparent lack of vigour, beyond, of course, the smallness of the bunches as compared with those produced during the first twelve years. In pruning Vines the first season after planting, as, for instance, Vines planted in the autumn of 1892 and pruned during the coming week-end of the year, the usual plan to follow is to cut to within three eyes of the bottom wire connecting the rods with the roof of the house. A leader for the next year's growth is thus provided, as well as one pair of side growths. This method of pruning lays the foundation for the future rod. In some vinerias the bottom wire is 2 feet from the border, and sometimes more or less, as the case may be. Vines managed on this principle are allowed to carry one bunch each the first year. The second year, if the roof is a long one, five eyes may be left, which would be two pairs of side shoots and the leader. Vines of this strength would safely carry four bunches, if they were not too large; say 8 lb. in the aggregate would not be too great a strain for vigorous Vines to bear. This is the correct method to follow if the Vines are intended to bear freely for a number of years, but if the first ten years are only to be considered, a greater length of rod may be left at each pruning, and a greater weight of fruit could be taken from the Vines also. "J. C." will be able to discriminate between the courses to follow from the above explanation of the methods adopted.—S. P.

—So far you have treated your Vines admirably. If you avoid overcropping them the next and succeeding years you will have a vigorous lot of Vines that will do credit to your forethought and careful management. Four large bunches or six smaller ones is as many as they ought to carry next year. The rods may increase 3 feet in length every year until they reach the top of the house. This, however, is the maximum growth that should be allowed.—J. C. C.

4393.—**Pot Vines**—As a rule, pot Vines are not much used after they have fruited one year in the same pots; but, of course, that depends on the quantity and size of bunches. If you can replace the present stock with young ones by all means do so; if not, shift those you have into other pots 3 inches larger, or, failing this, make the hole in the bottom of the pot larger, and let the pots rest on a bed of loamy soil 6 inches thick. Whichever you do, let it be done at once.—J. C. C.

4280.—**Fig trees under glass**—I suspect your trees grow too freely owing to their having too free a root run. To grow Figs well the roots must be cramped somewhat by enclosing them in a pit, or running a wall across a part of the border, thus limiting their run to a certain portion of the border. Abundance of water is necessary, both at the roots and overhead, to keep the foliage fresh and free from insect pests. Until the roots are in a matted state within the prescribed limit of the border manure is not required, and only then when the fruit is swelling. If the trees are carrying a full crop copious supplies of liquid manure will be an advantage to them as well as a mulching of horse manure spread over the surface 2 inches thick. Some care is necessary in pruning Fig trees; the branches should be kept thin, removing those that have borne fruit and replacing them with younger, but by no means overcrowd them.—S. P.

—There is no fruit grown under glass that requires so much skill as Figs to get them to fruit well and regularly. If they have too much root-space nothing will prevent them making a large amount of wood, which does not ripen properly, and consequently forms no fruit. If the roots do not get all the water they want, a good portion, or all the fruit, will drop off when young. The branches of Figs also want skilful and timely management, or the result is overcrowding, and then a failure in the crop is sure to occur. Not knowing how you have treated your plants or any of the conditions under which they are growing, I can only suggest that you thin out the growth considerably, and if there is a good second crop of fruit showing, pinch off the points of the bearing shoots, as in such a season as the present there should be no difficulty in ripening the second crop. When Figs are growing in pots, or narrow shallow borders, they do want a considerable quantity

of stimulants in some form. For pots liquid manure is the best, and for borders a top-dressing of loam and crushed bones. Excessive vigour in Fig trees can only be checked by severe root-pruning. This should be done as soon as the leaves have fallen. Early in the spring trees so dealt with should have a thick mulch of manure spread on the border. With regard to the quantity of water they want, the very character of the leaves indicates that it must be considerable if they are to be properly sustained, and not only the roots but the branches also require constant syringing.—J. C. C.

4251.—**Gathering and storing Pears**.—To gather and store Pears successfully, it is well to take a flat basket every morning during the autumn, and go round the tree trying the fruit. To do this, one of the ripest-looking fruits should be selected, and lifted sharply in the hand to a horizontal position; if this movement, without pulling the fruit, results in the Pear being left in the hand, then it is in a proper state to store, although in some cases it may take months to ripen. All Pears are the better for storing, though it may be in the case of the early varieties for a few days only, for if left on the tree the flavour is not so fine, moreover, the wasps usually take more than their share of the spoil if they can. An enormous proportion of the fruit grown in England is lost or injured by thriftless ways of gathering and storing, and it is sometimes difficult to persuade a gardener, if ignorant, that Pears must not be piled one on another. The slightest bruise will result in rotteness later on, and the fruit will never appear at dessert, unless gathered at the right time and in the right way. The rough and ready plan of picking in all the fruit on a tree on the same day, and throwing it into deep baskets, should not be allowed, especially in the case of valuable wall fruit. Each fruit has but two or three days in which it should be gathered, if plucked before this it will shrivel, and never come to perfection; if left on later it will fall to the ground and become bruised. It is, therefore, specially necessary to give daily attention to the trees during the time of their ingathering. The best place to store is a dry old cellar, where it can be laid on newspapers, each fruit separate from its neighbour, in the dark, and with an even temperature, never going below freezing-point. It is also necessary to visit the Pears constantly, removing any fruit which may begin to shrivel or rot at once, while selecting for dessert those fruits that are ripe.—I. L. R.

TREES & SHRUBS.

CATALPA BIGNONIODES.

This Catalpa, better known by the specific name of *C. syringifolia*, stands out conspicuous as one of the very few trees that can be found in bloom in the month of August, while it is certainly the showiest of them all. It possesses many desirable features, and is unsurpassed as a medium-growing lawn tree for standing singly. It develops a broad, yet rounded head, clothed with ample foliage, while the terminal panicles of blossoms are disposed a good deal as in the Horse Chestnut. As in the case of the last mentioned, the individual blooms are wonderfully pretty on close inspection, those of the Catalpa being white, spotted and marked with purple and yellow. It is also known as the Indian Bean-tree, from the long Bean-like seed-pods, which are, however, produced but sparingly in this country, though in warmer districts they are very numerous and form a distinctive feature. Another point greatly in favour of this Catalpa is that it is a capital smoke-resisting tree, and is consequently one of the limited number of trees that are available for planting in the neighbourhood of large towns. It may be met with in a thriving state in various soils and under different conditions, so that it is by no means particular in this respect; still, more luxuriant growth and richer tinted foliage result when it is planted in a deep free soil and not subject to drought during the summer. A second species, or probably a form of this last, is *C. speciosa*, which has been highly spoken of in America as a quicker growing tree of hardier constitution than *C. bignonioides*. But whether it will form such a handsome specimen when old remains yet to be seen. To

the lover of golden-leaved trees, the yellow-foliated variety of the common Catalpa has much to recommend it, for it is of a pleasing colour and does not burn by exposure to the full rays of the summer's sun. The Eastern species—*C. Bungei* from China, and *C. Kumpferi* from Japan—are smaller growing than the preceding, and as far as can be judged at present, are neither of them likely to attain any great degree of popularity. T.

4303.—**Treatment of an Araucaria**.—You may as well destroy your Chilean Pine as soon as it gets unsightly. When the *Araucaria imbricata* once begins to lose its bottom branches there is no help for it. This Pine delights in a deep and cool soil, and if the subsoil be clayey or constantly wet, as soon as the main roots reach this the results will be shown in what you describe. They are rather deep-rooted plants, although a few strong roots may often be seen running near the surface—a feature in all of the Pinne family. It is very disappointing when a fine tree, about a three-parts specimen, goes in this way; but the majority of them do. They will grow in any soil up to a certain stage, but if the subsoil is not suitable they invariably fail just when they have become really handsome plants.—P. U.

—The dry season has probably had something to do with its present condition if the change has been sudden. Checks either from frost or drought are bad for this tree. The *Araucaria* is in many positions an unsatisfactory tree anyway. It rarely lives to be old.—E. H.

4299.—**Azalea mollis on a bank**.—The position is rather cold for this Azalea, which is not very tender in itself, but the flowers get much cut up by early frosts. But you may possibly devise some means of shelter, which we cannot do unless on the spot. I am pleased to know that you are interested in the hardy Azaleas, and *A. mollis* has been kept in the background partly because of its reputedly tender character, but this is not the case. It has lived through unharmed recent winters, and if you can get a group of them in full bloom untouched by frosts the effect will be very fine. The range of colours is extensive, passing from yellow to intense crimson, and in time we shall get many other tints. *A. mollis* should be placed in cool, quiet shady corners, where they are free from winds and early frosts. As regards soil, peat is, of course, the best, but good fibry loam will do well. The *A. mollis* hybrids are usually now grown in pots, especially on the Continent, and for this purpose they are well adapted by reason of their great freedom of flowering.—C. T.

Clethra alnifolia.—A short time since a correspondent in GARDENING asked a question as to the hardihood of this shrub. This note may, therefore, be of more than usual interest, as I saw it in a Surrey garden, not more than twenty miles from London, in full bloom a few days ago. Of course, this must not be taken as proof of its complete hardiness, as the garden in question is peculiarly situated, being much sheltered by Rhododendrons, and surrounding woodland. Still, in recent hard winters Veronicas have suffered greatly, but the *Clethra* stood out unharmed. It makes a very beautiful shrub, the leaves of a bright-green shade, and the flowers, produced thickly in spikes, white, or creamy-white. When in a light soil, and not too exposed, it will succeed well. This *Clethra* has been introduced many years from North America, as it was brought over in 1731. If any readers are interested in it, and can give the necessary requirements, it is an interesting feature in the garden.—C. T.

The Siberian Crab.—This is a lovely tree, and lately I saw on the outskirts of a small lawn a specimen almost breaking down beneath the burden of fruit. It is named *Pyrus baccata*, and there are varieties of it. A specimen on the lawn is beautiful at all seasons, as the flowers are attractive, followed by a large display of fruits, which are now beginning to change to a bright crimson colour. Of course, the crop differs from year to year, but this particular tree was a perfect picture. I need scarcely say that this *Pyrus* is as hardy as anything that grows in the garden, as it was introduced from Siberia in the year 1784. The growth is remarkably graceful, and the tree does not make unattractive growth. It is found peculiarly in the surroundings of the lawn.—V. C.

OUTDOOR PLANTS.

THE WHITE GOAT'S RUE.

This is a very pleasing plant, perfectly hardy, and producing a wealth of white, Pea-like flowers. It is perhaps rather too tall for small gardens, but its habit is very neat and compact, whilst the spikes of pure-white flowers are produced over a comparatively long season. It is valuable also for cutting, and a pretty combination is a cluster of Ever-raising Peas, the latter

OUR READERS' ILLUSTRATIONS: The White Goat's Rue (*Galega officinalis alba*). Engraved for GARDENING ILLUSTRATED from a photograph sent by Mrs. Bradley, Akeley Edge.

in the centre of the vase, with the *Galega* on either side, and with its own foliage. It should not be formally staked, as the plants lose their graceful character. Few things look more wretched when thus bunched up. It comes perfectly true from seed, and transplants well any time after the stems have died down.

CARNATIONS.

GENERALLY we place the Carnation second to the Rose; but in this year of extreme heat and drought it has proved with us the first flower of the garden, and never was it more brilliant and beautiful. It has been a sorry season for Roses. The first blooming of many kinds was most inferior, although it should be said of the Teas, the true perpetual bloomers, that they are now beginning to make amends, and promise a fine display very soon. The great summer Roses, however, have come far short of the mark: but Carnations have given such a display and effect of colour as could not be surpassed by any flower. The year has suited them, unless it be in light sandy soils; but these are unsuited to the flower, although fair results are obtained in moist seasons. This season proves that the powers of endurance which characterise the wild Carnation living on old walls are not entirely lost in its much improved offspring of to-day. Since I made my plantation last autumn, beyond keeping free from weeds, nothing has been done to them, and the deep, holding soil in which they were rooted carried them safely through the drought until near its close, when signs of distress were apparent. One good watering and a slight mulching to conserve the moisture have sufficed since. But easy as is the culture and great the results from a minimum of care, especially as compared with the ever-recurring expense and trouble attached to adorning the garden for a short period with tender things, the fact remains that there is abundant room for the extension of Carnation culture in English flower gardens. The popularity that the flower

has long enjoyed has been as a florist's flower, and till recently nothing was thought of its value for the garden. The florist was, and is, concerned chiefly in the flower as a unit, varied in colour, and conforming, as far as possible, with certain ideals. For example, the wild Carnation has fringed petals, but the florist's ideal is a flower perfectly smooth and regular in form and outline. This is, to some degree, essential when each petal partakes of two or three tints, and the flower is studied individually as a thing of colour. For the flower garden, however, we must regard the Carnation from a very different standpoint, as the florist's varieties come very near each other, and through their variegations there is an indistinctness and want of decided effect. The varieties that formerly were regarded as of least importance are now all essential. These are the *Sels*. There is nothing to equal them for bold and decided effect of colour when massed in the garden, and if they are not wholly used they should at least predominate. Some thought that hardy flower gardening would be colourless, but

SELF CARNATIONS give colour as brilliant as ever were produced by gaudy *Pelargoniums* with all the additional charms of fragrance and fine form. The hard and fast lines that guide and govern the florist in the selection of his finer kinds must be almost ignored. A few cardinal points should be observed beyond that of colour, such as robust habit and the form of the flower. A defect of many modern varieties was pod bursting, and it was tolerated among the show varieties, the flower when shown being held together by an elastic band or tie. The garden Carnation, next to being of decided tint, should not be a burner, because out-of-doors wind and wet—in fact, wind alone—soon reduces it to a ragged, shapeless thing. It is a defect of formation unknown in the bold type, and of possible elimination even among modern kinds. I notice with satisfaction that of many new and recent kinds on trial this year only a very few will be rejected on account of this bursting propensity. In the midst of our enjoyment of Carnation flowers there arises the necessity for immediate preparation for another season's display. The details of successful culture are few and simple, but must be diligently observed, and of these the most important now is layering. A great many growers have completed this operation only, however, by reason of the abnormal season. The present is the time that the work is usually performed. The importance of annual layering is that old plants frequently perish and are rarely as good the second year, whereas a young, well-rooted layer is absolutely hardy, and no cold will kill it if the kind is naturally robust. Layers put down at the present time root abundantly in six weeks, and this enables planting to be taken in hand after the middle of September. If it can be completed in that month all the better. With such an early start success is as far secured as our own efforts can assure it. The sight of splendid groups of plants through autumn and winter gives much gratification and relief from anxiety when one looks upon flower-beds and borders furnished for another year with occupants that are happy and flourishing through all the changes of an English winter and spring. A. H.

4284.—Carnations and Picotees.—The question is often asked in GARDENING as to the difference between Carnations and Picotees. It is a mere difference of degree, after all, and I may say that the difference between Carnations, Picotees, and Cloves is one only of colouring. The parent in each case is *Dianthus caryophyllus*, and these latter-day acquisitions have been secured by a careful system of hybridising. Of the three the more important is the Carnation, although much attention seems now to be given to the Picotee, and the chief classes are *Bicolors* and *flakes*. Of the bizzarres there are scarlet, crimson, pink, and purple; there are scarlet, rose, and purple flake. In

the bizzarres two colours are represented, either in flakes or stripes on a white ground; but in the flakes the distinctive colours are laid on a white ground, and of the three the rose are the more beautiful in my opinion. A rose flake is a charming flower, rose colour against pure-white. The Clove is a self-coloured flower, of which the type is the old crimson Clove, as beautiful for its fine crimson colour as for its rich Clove scent. Its fragrance is delightful. The Picotee is also practically a Carnation. This may appear a paradox, but it is a form of the Carnation, the flower usually white, but it may be varied, coloured at the margin. On the density, or rather the breadth, of the marginal colour depends the class to which it is allotted. There are light, medium-edged, and heavy-edged. Exhibitors class them under various colours—purple, red, and rose, or scarlet—of each colour there being light and heavy edges. The perfection of a Picotee is where the ground is perfectly pure, without colouring, except at the margin, where it must be well defined. The yellow ground Picotees are distinguished by the yellow groundwork to the flowers. As regards the Pink, no mistake can be made between this and the Carnation. The parent of this is usually supposed to be *Dianthus plumarius*, and there are the border and laced kinds. The border Pinks are represented by such varieties as Mrs. Sinkins, and therefore, *sels*, but the show kinds are laced or margined with various colours—red, purple, maroon, and other shades on a pure-white ground.—C. T.

CAMPANULA PUMILA.

This is one of the most charming of the Bell-flowers, and appears to be a very variable species, variously known in gardens as *pusilla*, *capitata*, *linifolia*, *waldensis*, &c. It does equally well in the flower as the rock garden, and never fails with an abundance of its white bells. In its most common form it is a dwarf creeping plant, forming tufts of small leaves very pale-green, from which spring the hundreds of flowers which adorn it during the summer months. The clump here represented was brought to its present home from Switzerland, and in the various districts of Switzerland where it is

OUR READERS' ILLUSTRATIONS: A clump of *Campanula pumila*. Engraved for GARDENING ILLUSTRATED from a photograph sent by Mrs. Newman, Hazelhurst, Haslemere.

found in plenty, it is most variable in height, size of leaves and flowers, and not unfrequently we found the pure white form wild. The white variety is very charming, especially if one gets a mass of it, and it is very easy to grow.

4279.—Single Begonias as cut flowers.—One thing is to cut the flowers a short time only before the show and keep them in a cool place. Now do not remember, that flowers of all kinds have faded very quickly this

URBANA-CHAMPAIGN

year owing to the heat, and so we are not surprised to know that the flowers of the Begonia are behaving in the same way. I have never exhibited Begonias, but it is the practice with some growers to wax the ends of the stalks, and the old-fashioned plan of cutting off a small portion from the bottom is good.—C. T.

— Begonias will not set long in a cut state. There is no better way than to keep them in water, with as little of the stem out of the water as possible.—E. H.

— It is the nature of these flowers to fade within a very few hours of being cut, unless kept in water, when they will last some days. Could you not send them to the show in water, and set them up with the stalks in small tubes or phials of water? Otherwise place them, when cut, in a box with a lid, laying them on damp (not wet) wadding or Moss. If allowable, they will keep fresh for some time if stuck in a bed of damp Moss, and present a much better appearance as well than on the usual boards or stands.—B. C. R.

4295.—Plants going to leaf.—You do not say whether the position in which they are placed is shady or otherwise. If shady, or the soil is too rich, perhaps you have manured it too much; this will cause a greater profusion of foliage than flowers. Bedders do not need a rank soil, and certainly shade is hurtful.—C. T.

— The difficulty this season in most gardens has been to get plants to grow freely. If plants, such as "Geraniums," have gone too much to leaf, it must be in consequence of the manure, and this will disappear next year. The roots of trees would have an opposite effect, though if the trees threw much shade, the plants would be drawn up, and they would not flower so well. Possibly this might have had some effect.—E. H.

4296.—Everlasting Pans.—These can be raised from seed; but the quickest mode of propagation is by division of the long trailing roots which shoot up readily when planted in light, rich soil. The white variety is much less common than the well-known rose-coloured form.—A. G. BUTLER.

— These are propagated by seeds and by division of the roots just as growth is moving in spring. A large old plant will cut up into a good many, and seeds usually come pretty true to colour. The seeds from plants growing in a sunny position grow the best, being better ripened.—E. H.

4296.—Plants for a rockery.—Your question necessitates a rather lengthy answer. You cannot do great things now, but in the coming autumn and winter you should work hard to make it bright and attractive for next spring. I will give as much information as possible to you in a small space. If you are going to plant Ferns, select some of the choicer kinds, such as *Osmunda regalis*, *O. cinnamomea*, &c., which are very beautiful in a moist position, where they can get a fair amount of shade. I know of one rockery near London which is made externally beautiful with them, but have the Ferns only in the more shady spots. Here are the names of a few things to plant: Of Campanulas or Bell-flowers, very charming are *C. pumila* (white), *C. persicifolia*, *C. pyramidalis*, *C. carpatica*, *C. muralis*, and many others. But these may be planted first, and they will thrive in ordinary soil. Try and establish the Balearic Sandwort (*Arenaria balearica*) upon the facings of the stones. It is like a little Moss, running over them and hiding their harshness, whilst in the summer the flowers are produced in profusion, white, starry, and very pretty. *Achillea ptarmica*, The Paarl (double white), *A. mongolica* (white), large flowers comparatively; *Adonis vernalis* for spring, its flowers yellow, set amongst finely divided leafage; the Rock Madwort (*Alyssum saxatile compactum*), a perfect shower of golden flowers in spring; *Anemones* in variety, especially the pure-white *A. japonica* alba. But the type which has rose flowers and this variety make a good contrast. *Aquilegia chrysantha* (yellow), *Arabis alba* (white), very charming; the Prophet flower (*Arnebia ochioides*), on dryish soil and sunny position; *Aster alpinus*, *Aubrietia Campbellii* (purple), and *A. Leichtlini* (rose), the King Caps or Calthas, for a marshy spot—they are very rich in spring with their deep-yellow flowers; *Oenothera montana* alba is suitable; also *Chelone barbata*, red flowers; *Corsopius lanceolata* (rich yellow); alpine Pinks, which require special situations—they like sun and a pretty light soil—established against cool grey stone they are very charming; *Dictamnus fraxinellus*, both type and white kinds also, and other known, perhaps, as the *Fraxinellas* are very

good plants; whilst you may plant also the Sea Hollies, particularly *Eryngium planum*, which has smaller flower-heads than the others, but they are produced very freely; Dog-tooth Violets, charming in the lower parts of the rockery, where their flowers can be well seen; *Gentianella acaulis*, or the *Gentianella*; *Geum coccineum planum*, a very hardy and bright scarlet-flowered plant; *Gypsophila paniculata*, producing a multitude of small white flowers, a light graceful mass; *Heuchera sanguinea*; *Iris* in variety; spring-flowering bulbs; the August-flowering *Galtonia candicans*; *Lupinus polyphyllus albus*, which has fine spikes of white flowers; *Lythrum roseum superbum*, rich rose flowers; (*Eootheras*, (*E. Youngi* especially); *Polemonium corololum*; *Primroses*; *Auriculas*, alpine species and the handsome border kinds; *Prinnia japonica*; *Saxifraga* in variety; *Statice latifolia*; *Trollius europaeus*, or the Globe-flower; and *Veronicas* may be named. These will be a guide as to your selection, but as years go on you may add many other things. You cannot make a good rockery at once. I shall be very pleased to assist you in the future. Remember that half the battle is to make the foundation of the rock garden well. There must be plenty of soil, though the usual thing is not to have sufficient. In this body of soil the plants can find plenty of room to root and develop.—C. T.

— With a judicious mixture of *Saxifraga*, *Arabis*, *Anemones*, *Solomon's Seal*, *Spiraea*, *Crepiger*, *Jenny*, *Houseleeks*, *Rock Pinks*, *Panicles*, *Violets*, and, of course, *Ferns* you can make your rockery presentable throughout the year. My rockery is about 90 feet in length, and has the sun upon it all day; but, with attention to watering in the hottest weather, it always looks beautiful and is no trouble.—A. G. BUTLER.

4298.—Plants in a Rhododendron bed.—You can grow Lilies to perfection. It is exactly the spot for them, the position being sheltered, and the Rhododendrons are protection to the rising Lily shoots in spring. You must have the taller Lilies in the beds, and it will not be necessary to provide special soil, as it will be already of a peaty character, or at least should be, and thus suitable for the flowers. *L. auratum* is one of the finest for the purpose. It blooms in August and September, and makes a splendid display of colour, the noble spikes rising out of the wealth of leafage. *L. superbum*, a very variable and beautiful Lily, the forms of *L. tigrinum* or the Tiger Lily, *L. speciosum*, and *L. pardalinum* are all eatable—in fact, all the taller kinds, as the earlier types are apt to get smothered up. During recent years the Lily has been much used for planting amongst shrubs, especially Rhododendrons, and the aspect of gardens towards the close of summer and autumn has been in a measure changed by their free use. Amongst the dwarfier shrubs, *Ericas*, *Kalmias*, etc., may be planted such Lilies as *L. longiflorum*, usually grown in pots, but beautiful in the open, and varieties of *L. Thunbergianum*. You might have a lovely Lily garden with little trouble. The question of expense, of course, depends upon how much you are prepared to pay for the choicer kinds. But *L. auratum* bulbs can be purchased moderate in price.—C. T.

— Lilies and Irises would do well, and you can carpet the surface of the bed with *Panicles* and *Violets*.—A. G. BUTLER.

— Plant bulbs, such as Snowdrops, Daffodils, Lilies, *Hyaacinthus candicans* would look well now. Lilies candidum, auratum, and others would brighten up the dark foliage in summer, and the Snowdrops, Daffodils, and Tulips in spring.—E. H.

— The best plant for this purpose is *Lilium auratum*, which invariably thrives in such a position, either planted permanently or planted in pots. If an edging is wanted, use *Gladioli* and *Begonia*.—B. C. R.

4297.—Improving a tennis lawn.—By far the most powerful and quick stimulant for Grass of any kind is nitrate of soda. It should be crushed finely and sprinkled over the surface at the rate of 2 owt. or 3 owt. to the acre, or say 2 lb. per rod, and if rain follows, or it is well watered in by hand, in a week or ten days the Grass will be seen to take on a deep green colour, and begin a very luxuriant growth. The effect is not fugitive, nor does any reaction follow, unless an excessive amount has been applied; but, on the contrary the Grass will grow stronger the next year as well. A burnt-up or worn-out lawn will quickly revive under the same treatment; another method being to give it a good weather cure or two good waterings with a good solution of the nitrate, one ounce to each

gallon. If at the same time, or soon afterwards, a sprinkling of soot and bone-meal mixed, or soot and superphosphate of lime, the effect will be more permanent, and half an inch of leaf-mould or road scrapings sifted and spread over the lawn or meadow in March or April will still further strengthen and improve the turf. The spring is the best time, as a rule, to apply "stimulants or top-dressing," but a little soda and soot also may be applied now, or whenever necessary or most likely to be beneficial, except during the late autumn and winter.—B. C. R.

4295.—Making a lawn.—Mow the rough Grass off, and have the surface pared off with a breast-plough, or in some other way. When the pared-up material is dry burn it; keep the ashes to spread over the surface when the Grass-seeds are sown. During the autumn and winter cart a good dressing of manure and dig it up a good space's depth, burying the manure. At the same time work the surface of the ground into the required form, and let it lie rough till March. Then break it down fine. Scatter over the ashes, and sow thickly with not less than 4 bushels of fine Grass-seeds, and when the surface is dry roll it with a moderately heavy roller. If any part of it is turfed, the turf may be laid in August, but the seeding will be the cheapest, though turfing will make the lawn fit for use sooner. If a lawn for tennis is required on any part of it the ground should be made quite level, and it will be better to have that piece turfed and seed the remainder. If any alteration is made in the level have the good soil reserved to go on the top again, so that the turf may be all of the same colour and strength.—E. H.

INDOOR PLANTS.

LAPAGERIAS.

THIS is a genus of greenhouse climbing plants whose beauty is unsurpassed. It contains only one species, but of this there are many varieties, and to pick out the most showy ones should be the care of the grower, so that the most desirable forms are grown together. The pure white variety presents a much better appearance, and the flowers are more telling when hanging from the roof side by side in clusters than in any other way. The types sent by "T." are very nice, but too light in colour, and the flowers too short in the tube to look well beside the ordinary white variety, for this plant looks best when seen beside the "Nash Court" variety of roses, which Mr. Laing has at his nursery at Forest Hill. The *Lapageria* succeeds best when planted out, and the border should be made up thoroughly with broken bricks and other drainage material. The soil, which should be good turfy loam and peat, must be chopped up roughly, and all must be pressed down firmly. Provide a good outlet below for the water to get away quickly, for the plant will remain quiet and dormant for a very long time if stagnant water is suffered to lie about its roots. When placed in good genial soil, and with good drainage material it sends out long and strong shoots from the base which will grow up quickly and soon cover the roof of the house. *L. rosea* and white variety should be planted alternately, and the varieties of *L. rosea* that are good and showy can also be planted with it. Different kinds can be interwoven as the shoots grow up. "T." should select for these plants a house with a cool, shady aspect, and give them plenty of water at the roots, also overhead from the syringe. The *Lapageria* is very liable to attacks from thrips which are most hurtful.

J. JARVIN.

4305.—Plants for a hot greenhouse.—Under present circumstances, little except Cacti and a few other succulents will do much good, with perhaps a few *Aspidistras*, *Draenas*, and the like. If you really want to grow Ferns, the floor must be covered with a layer of ashes, or something that can be kept almost constantly moist, and some tanks or shallow pans of water fixed under the stages would be a further improvement. With the glass rather heavily shaded, and plenty of water, Ferns, foliage plants, and climbers ought to do well. Failing all else, I should fix a finely perforated pipe along the roof, to which water could be turned on as will, and throw a constant fine dew all over the place when necessary.—B. C. R.

PRIMULA OBCONICA.

This is a well-known plant now, and a very pretty thing for the greenhouse. It is easily raised from seed, and seedlings vary in colour and size of bloom; but the prevailing shade is soft-lilac. It is not a great success in the open, and the flowers are really too pale for the garden. Something more effective is necessary in the open. It will bloom throughout the winter—in truth, may be called perpetual flowering—and has been intercrossed with other kinds, so that in time we shall get a very interesting race. It was found by Mr. Maries, a well-known collector, in China, and is very distinct. It is a good amateur's plant, and useful for quite a small greenhouse.

4275.—Culture of Cactuses.—I have given as full particulars as space will allow about these interesting plants. They are strange things, and a new love is springing up for them. They can be grown in rooms, and one sees fine examples in a cottage window where they get plenty of light, and are free from the influence of frosts, whilst the atmosphere is not too moist. The majority of the Cactuses need a dry air, as it is under these conditions they thrive in their native home. They attain luxuriance in hot, burning sand on the plains of Mexico, and those conditions must be imitated as far as possible when they are under cultivation. The plants may be grown well in a greenhouse, where a temperature, say, from 45 degs. to 55 degs. is maintained. Give them free exposure to the

dry. They grow slowly, as is characteristic of Cactuses in general. Spring is the best time for sowing the seed.—C. T.

4277.—Winter flowers.—The selection is necessarily somewhat limited, but in late November and throughout December you can have some *Chrysanthemums* from late struck cuttings and also *Zonal Pelargoniums*, Dutch bulbs, *Cinerarias*, *Cyclamens*, and Chinese *Primulas*; but bear in mind the importance of not crowding the plants too much, as this means a poor growth. In the winter they must get as much air as possible; also keep such things as I have mentioned as near to the glass as possible to encourage a stocky, well-developed growth. If this is not done they get drawn, and the flowering as a result suffers greatly. Air and light are two precious attributes of plant growth in the winter season. Avoid, however, cold currents of air. If your house is fairly large you can add to the above *Camellias*, say a specimen of the old double white, still one of the most useful flowers in cultivation, although *Camellias* are not so popular as in years gone by. The fragrant yellow-flowered *Cytisus racemosus*, which is very easily grown, and makes a bright showy plant, should also be included, besides the white-flowered *Deutzia gracilis* and *Acacia armata*. You should make good use of bulbs, such as *Deffodils*, the Trumpet kinds in particular, and make up a few pans of the little *Glory of the Snow* (*Chionodoxa Lucille*), *Iris reticulata*, and *Snowdrops*. You may get a charming feature thus. You may also

will, however, find it difficult to fix a tank to the existing pipes without pulling them apart. Why not pack some rubble round and over the pipes instead of a tank, and on the rubble a bed of tar or Cocoa-nut-fibre refuse, to use as a plunging material. A bottom-heat of 90 degs. will suit the majority of stove plants.—J. C. C.

4289.—Treatment of Diosmas.—It is refreshing to get an enquiry about this sweet-smelling, old-fashioned plant, for one rarely sees it now, yet for beauty of leafage and for associating with cut flowers in small glasses there is nothing to surpass it. It may be useful to say that it is a hard-wooded greenhouse plant of the easiest culture. All it wants is a shift into a larger pot every year. The half-ripe shoots made into cuttings at this time of year, and dibbled into sandy soil and kept close and shaded, strike root in four or five weeks. If your plant is pot-bound it is quite easy to cut it hard back now, and give it a larger pot in the spring; but if it has been recently potted it will be better to defer the cutting back until next February. Now the summer is so far advanced you had better keep the plant in the greenhouse.—J. C. C.

— It is too late for *Diosmas* to break now. Prune in spring, and help in a warm, close house.—E. H.

4302.—Pelargonium cuttings.—These are very simple to strike. All you need is wood about half ripened, such as side shoots breaking from a plant in bloom. Any soil of a sandy nature should do. I do not keep them close, nor do I place them on a shelf. The ordinary treatment used for the variegated form of *Zonal Pelargoniums* will answer admirably. You have probably kept them too wet. No *Pelargonium* need much water while striking; nor should they be frequently sprinkled. The form of their leaf, also the numerous downy hairs upon the same, hold moisture much too long. Have the soil fairly moist when inserting the cutting, then give one thorough watering and wait until they are quite dry before repeating.—F. U.

— These will strike freely enough now. Place the pots in an open situation in the open air on a bed of coal-ashes, and keep the soil moist. Cuttings cannot root without moisture. Sprinkling the foliage is not sufficient.—E. H.

4307.—Smilax asparagoides.—This is very easily cultivated, and readily raised from seed. I also find that it ripens seed freely, which if sown in the month of March in an ordinary greenhouse soon grow into useful-sized plants. You had better keep over your seed, or a part of it, until next spring, or you may lose the young plants through damp in the winter. I obtained my first lot from purchased seed.—J. C. C.

4300.—Treatment of Abutilons.—These are strong-rooting and somewhat hungry subjects, requiring to be grown in rich, loamy soil, with plenty of liquid-manure after the pots get full of roots. Shift them at once into pots 4 inches larger, watering them carefully for a time, and they will flower beautifully from September to Christmas, or later, especially with a genial warmth when the weather grows cold. If the growth is straggling, cut them back first, and repeat when the young shoots are an inch or so long.—B. C. R.

— From the presence of the roots it appears as if the plants required repotting. Give a good shift now in good soil.—E. H.

— Plenty of pot-room and liquid-manure twice a week in the growing season will produce the result you require.—A. G. BURTON.

4309.—Pelargonium "Master Christine."—The true variety of this name has no perceptible zone on the leaf, which is of a pale or yellowish-green. The flowers, which are produced in large and numerous heads or trusses, are of a soft, rosy-pink colour, with a small white spot on the two upper petals. Another peculiarity is the unusually thickened base of the flower-stalks, and the curiously-rounded stems with large nodes.—B. C. R.

4281.—Fressias in a cold-house.—Yes; it is quite possible to grow these sweet-scented bulbs in a cold-house. They are almost hardy, and the slight protection is quite efficient. When growing them in this form, however, it will be well to keep them more backward, and I would not pot up the bulbs until November. Sort your bulbs into two sizes, placing six or eight of the largest into a 4-inch or 5-inch pot. Use a sandy compost of leaf-soil and loam, and

Primula obconica.

sub, and as regards soil use a mixture of loam, not heavy, and sharp silver-sand, adding a small quantity of broken pieces of brick to keep the compost thoroughly porous. There is no need to go in for elaborate composts—lime and so forth—as often these special preparations are the reverse of beneficial. The plants are best repotted in early spring, say March, and in potting remove as much as possible of the old soil from the roots, cutting off dead or dried up pieces, as these are of no value to the plant. The rock upon which the majority of amateurs split in the culture of Cactuses is the watering. During the winter months about once in three weeks will be sufficient, but during the summer more frequent supplies are necessary—in the very hottest weather about every day. It is a mistake to let the plants suffer from a continual dryness of the soil, otherwise they shrivel, and this is most injurious. You ask about propagating. Well, there are three ways, namely, by grafting, cuttings, and seed. The best and most usual plan is by cuttings, a good way in the case particularly of the *Cereuses*, and, as is well-known, the *Rhiphyllum* is commonly grafted. In taking cuttings, take off young growths in the spring or summer months, and let them remain in a sunny spot until the cut place has healed over. Then put in pots filled with light soil; do not water, but syringe lightly overhead. Cactuses may be raised also from seed, which should be sown in a light loamy soil in small pots. Place in the warmest corner of the greenhouse. The seedlings make very slow progress, and will soon come to grief if not kept

grow the pinky-flowered *Primula obconica* and *P. floribunda*, which has yellow flowers, but these are, unfortunately, much affected by frosts.—C. T.

4278.—Begoniae in pots.—These are not troublesome to grow in pots, but you must be careful about the treatment as we get into autumn. Possibly you have kept the bulbs too wet, whereas, as autumn advances, less is required. When the shoots have died down none is necessary. This is a most important point, but amateurs sometimes blunder. The best plan when the plants have died down is to put them on their sides in the pots, and in such a position that it is impossible for water to reach them. They must not be exposed to frost, but a temperature of say 40 degs. will keep them perfectly safe. In the following spring the tubers may be turned out, and the old soil removed.—C. T.

— These are not difficult to keep through the winter if the tubers are well ripened, and the frost kept from them, and not excited by heat. If kept hot and dry sometimes they perish with a kind of dry rot, but when kept cool and dry they are safe.—E. H.

4308.—Forcing bed in a stove.—There is a diversity of opinion as to whether bottom-heat is necessary for stove plants. Personally, I do not think so, except for those who grow plants for exhibition. In that case such things as *Caladiums* and *Eucharis* are benefited by it. There are, however, many others that can be as successfully grown without bottom-heat as with it. If you think it necessary, a slat tank in which you require, and if you enclose the top pipe you will get all the heat you want. You

stand the pots beneath the staging until young growth has advanced a few inches. In case of hard weather through January and February, keep them as far from the glass as possible at night.—P. U.

4270.—**Basket plants for a cold house.**—*Vines elegantissima* is a very useful basket for cold house. Some of the variegated *Iris* are pretty. Whatever is used must be perfectly hardy. *Sedum carneum variegatum* and *S. Sieboldi* are suitable. I have seen *Jasminum nudiflorum* do well and flower most of the winter in a good-sized basket. Tender things, such as *Tropaeolum*, *Fuchsia*, *Petunia*, *Ivy-leaved Pelargonium*, *Heliopsis*, *Musk*, &c., may be employed in summer, and the hardy things for winter.—E. H.

4285.—**Fuchsias in a cold-house.**—In severe winters cover the bottom of the plant, with dry Ferns, or long dry litter will do. Never mind about the tops being injured. The new growth from the bottom will soon fill up again—all the brighter and stronger from being shortened back.—E. H.

4299.—**Double and Single Begonias.**—I should think that you have been very successful with the plants. They will continue to bloom until quite late autumn with proper attention, but when they commence to die down give less water. Do not, however, withhold it suddenly, and in time the tops will quite die down. When this is the case, put the plants under a greenhouse stage, where they will remain until the spring, say February. Then new growth commences again, and the tubers must be shaken out of the pots and repotted.—C. T.

4245.—**Arum Lilies for Christmas and Easter.**—These plants will not flower satisfactorily in a temperature so low as 40 degs. at Christmas, but "A Beginner" may easily have them early by utilizing the sunny window of a sitting-room with a fire, or a kitchen window. The plants, which are now gathering strength in the garden, should be given liquid-manure twice a week, unless the soil be very rich, between this and the beginning of September, when they should be potted up. Give good drainage and a rich compost, with pots which will only just comfortably hold the roots, packed in with the compost, leaving plenty of room for watering at the top. Single roots, in 7-inch or 8-inch pots, are the best for early work, as each will throw up its fine flowers about November, some needing to be retarded by placing them in a slightly lower temperature (that of the room should be from 50 degs. to 65 degs.), or they will flower before Christmas arrives. Directly the first flower is over the plants can receive a shift into a 10-inch pot, which will induce them to throw up plenty of blossoms for Easter, if they are well watered. Being semi-aquatic plants, they should stand in saucers of water, soot-water (in a thin, clear state) being given them once or twice a week, for they are hungry plants, and need a great deal of feeding to produce plenty of their lovely flowers. Green-fly is their special insect enemy. This should be kept off them entirely by the constant use of a small bit of soft sponge and lukewarm water, sponging the foliage, too, even when clear of green-fly, if it should become dusty. The plants should stand close to the glass of a south-east or south window; but during frost they should be taken further into the room, for they are very sensitive to a chill, being of so succulent a nature, and they will not open their blossoms in a temperature below 50 degs.—L. L. R.

Flowers in smoky London—How often do I see in gardening papers what will grow in suburbs, but how rarely what will grow in a real London garden, surrounded often by bricks and mortar, at times a perfect hailstorm of soot falling, elugs, wireworms, &c., actively at work. Roses, forsooth!—no such luck. Make annuals of them, and you may get a few blossoms. Still, flowers can be had, but, then alas! not many. First, I will name Single *Petunias*, and if a dry season, I guarantee a fine bud, if a good strain is procured. Ten-week Stocks, *Phlox Drummondii* (but not pegged down). The soil gets too foul, *Lobelia* (white and blue), *Calceolarias*, *Antirrhinums* do fairly; most of the *Campanulas*, and how grand some of them are! Double *Pyrethrums*, and early-flowering *Chrysanthemums*, Evening Primroses, a few *Lilies*, *Sulphur* and *Orange* in the spring, but perennials generally are a

failure. They seem to rot always. I have grown all of the above in a garden 15 yards by 12 yards.—METROPOLIS.

ROSES.

4233.—**Rosee not thriving.**—Rose William Allen Richardson has the peculiar characteristic of refusing to grow well without any apparent reason. *Marsébal Niel* and *Bouquet d'Or* are the same. One plant, grown exactly the same as another, and planted out under similar conditions, will thrive and produce remarkably vigorous growth where the other will remain at a standstill. You have chosen an excellent position for your plant, and are evidently treating it as well as you can. Cut it down close, and see if it will push up a strong shoot from the base. If not, transplant it elsewhere, and replace with another. It is more than probable that the second one will prosper.—P. U.

4249.—**Treatment of pot-Roses.**—I should out the plants back now, applying a little mastic to the cut, and completing the pruning in two operations—i.e., remove half of the growths down to two or three lowest eyes, and then serve the remainder in the same way about three weeks later. You will thus avoid checking the sap entirely, and consequently killing the points of many young roots. If the outlet of a full supply of sap is suddenly removed, the roots naturally suffer and stop their functions, in many cases dying entirely.—P. U.

4237.—**Rose "La France."**—You have chosen a very good position for this variety, and I cannot advise its removal. *La France* has been more than usually subjected to blight this summer as far as my observation goes. Crend as this old favourite is in some districts, it usually behaves with me as you describe, at its best being of indifferent quality. It is quite surpassed now by newer varieties, and although it is exquisitely scented, we can also equal it in this respect.—P. U.

4283.—**Rosee on a low wall.**—Yes; Tea-scented and Noisette *Roses* will do well upon your wall, and you will often get bloom there when it is ever with for the time upon more favourably-situated plants. Here are a dozen excellent varieties: *Anna Olivier* (buff and orange), *Mme. Faloot* (orange and apricot), *Marie Van Houtte* (yellow), *Perle des Jardins* (deep-yellow), *Dr. Grill* (salmon and orange), *Catherine Mermet* (pink), *Socrates* (fawn and peach), *Mme. Lambert* (red), *Souvenir de S. A. Prince* (white), *Innocente Pirola* (creamy-white), *Mme. Hoate* (pale-lemon), and *Sunset* (apricot and yellow).—P. U.

4272.—**Rosee for an outdoor border.**—There are many *Roses* which bear most handsome foliage, but you do not say if you wish those with a deep-green or with a reddish end bronzy shade. I suppose the latter. Almost all *Tears* possess beautiful foliage; perhaps the following are the best in order given: *Perle de Lyon*, *Souvenir d'Elise Vardon*, *Madame Bérard*, *Perle des Jardins*, *Sanset*, *Madame Faloot*, *Safran*, *Anna Olivier*, and *Marie Van Houtte*. Among the Hybrid *Perpetuals* the following are good: *Duke of Connaught*, *Captain Christy*, *Sir Roland Hill*, *Pride of Waltham*, *Earl of Dufferin*, *Countess of Oxford*, and *Charles Lefebvre*. In addition to highly-coloured foliage all of those named are also grand bloomers and growers.—P. U.

The quality of leafage on *Rosee* depends greatly on the soil in which they are growing, and whether you keep it free from injury by blight or insects. The following Hybrid *Perpetuals* are remarkable for their handsome leafage: *Charles Lamb*, *Captain Christy*, *Mrs. C. Laing*, *Magna Charta*, *Duke of Albany*, *Elle Gordon*, *Lady Suffolk*, *Lord Macaulay*, *Baroness Rothschild*, *La France*, *Red Dragon*, and *Ulich Bruner*. Many of the *Tea Roses* have bronzy leafage, which is quite distinct. The single *Japanese Roses* are worth growing for their foliage alone, while the leaves of the old *Maiden's Blush* and *Coleste* are of a glaucous colour.—J. C. C.

4298.—**Rosee not flowering.**—As your *Roses* in pots have grown so vigorously, I would advise you do not prune them so hard next year. There is no such thing as a *Never-blooming Rose*. It is a matter of cultivation,

as sooner or later all healthy growth must flower. But if you prune away strong vigorous wood, you are only inducing the plant to produce more of the same. Tie the shoots out in a horizontal position as you can manage, removing a very little of the wood, and you will in all probability get a good crop next year.—P. U.

—Immatured wood is the cause of your *Roses* not flowering. Turn the plants out-of-doors at once and place them in a sheltered corner, plunging the pots to their rims in a bed of soil or ashes. Prune them at the end of November, and then add another covering of ashes so as to bury the pots 2 inches deep. About the middle of February place them in the greenhouse again. It will be desirable to give the roots a change of soil, which you may do early in October by removing some of the old material and replacing it with fresh.—J. C. C.

4222.—**Manure for *Roses*.**—I have never used Bone-dust as a manure, but bone-dust is excellent upon stiff soil. It is very lasting in its effects, and makes a good change from other stimulants. A variety in manures is always better than applying the same year after year.—P. U.

Rose Augustine Guinolesseau.—I saw lately at an exhibition a splendid lot of flowers of this *Rose*, which is not often seen at shows, as it can scarcely be called an exhibition variety. These blooms, however, were very fine, although as to whether a certain variety is a good show *Rose* or no is of little consequence, if it is beautiful in the garden. The variety *Augustine Guinolesseau*, sometimes called the *White La France*, is certainly a lovely flower. I remember about three years ago seeing a large break of it in Mr. Benjamin Cant's fine nursery of *Roses* at Colchester. Every plant was smothered in flowers, each of good shape, full, white, tinted with a rosy colour in the centre, and deliciously sweet. This is a point of the utmost importance, and the *White La France* may rank amongst the most deliciously-scented of *Roses*. It is vigorous, free, and delightful for cutting.—V. C.

Fruit of the Japanese *Rose*.—It is not generally known that the fruit of this *Rose* makes very good jam, and when fully ripe it is not unpleasant to the taste, even when raw. It should be treated similarly to the *Guevas*. The *Japanese Rose* (*Rosa rugosa*) has got comparatively common, and in many gardens, not over large, one sees it. Certainly it is very beautiful, and seedlings vary greatly in colour from pure white (*alba*) to deepest crimson. I do not care for the purplish blooms, they are too "blue," and look dingy. A hedge of this *Rose* is a good barrier to cattle, although I heard lately that they will eat it. If this is the case the meal can scarcely be pleasant, each shoot being studded with sharp thorns.—V. C.

4220.—**Roses in borders.**—The old-fashioned *Monthly Rose* (*China*) I should say flower the longest, and next to these are the *Teas*, and the first to begin and the last to remain is *Gloire de Dijon*; but all the strong free-growing *Teas* will flower till quite late in the season in a deep, warm soil.—E. H.

—The Tea-scented and Noisette section, with the *Chinas*, are probably the latest bloomers we have, while they are certainly the earliest and most perpetual through the summer months.—P. U.

A valuable Dwarf *Fuchsia*.—A *Fuchsia* that will be grown freely in the future is named *Dunrobin Bedder*. It is very dwarf, and this is one of its chief charms, as the plant may be used in positions where other kinds are not admissible. It is peculiarly adapted for small gardens, as the plants do not grow more than a foot in height, and are smothered with crimson flowers, which show affinity to those of *F. Riccarteni*, one of the parents of this hybrid form. The leaves are very small, deep-green, and in contrast to the richly-coloured flowers. It commences to bloom in early summer, and does not cease until stopped by frost, whilst we should regard it as of value for pots, being so dwarf, bushy, and free. It is not known much to the public, but in time will get cheaper, and readers of *GARDENING* will welcome such a flower. Moreover, unlike the ordinary garden *Fuchsia*, this is quite hardy, and has lived out, unharmed, in recent winters. This is a good sign of its hardiness, as many reputedly hardy things have wintered in the open, or been entirely killed.—V. C.

HOUSE & WINDOW GARDENING.

BEAUTIFUL WINDOW GARDENING.

WHENEVER the general conversation turns to window gardening, it is quite a common experience to hear the familiar comment: "Ah! one should see how beautifully it is done in London." "In what part of London?" I have now and then asked. "Oh! in Piccadilly or in Kensington," comes the reply. "Oh! yes," I answer; "but a good deal of what you see in the localities named is not window gardening of the best and of permanent type, but is often carried out by the florists by the month or by the year." My notion of good window gardening is that carried out in its entirety by those who live behind the beautified pane. Again, the window-box or flower-pot style of window decoration is not always the most worthy of adoption, a remark that is simply proven by the illustrations here given. Window-boxes or flower-pots, which look at home in the cottage or villa residence, are somewhat apt to jar a little as seen in the windows of a castle or church; but no one could well object to the simple and appropriate window decoration by means of beautiful and naturally grouped climbing plants as here shown. The plant most evident on the central mullion and to the right is the Japanese Hop-plant (*Humulus japonicus*), an easily reared annual of less massive habit than is *H. lupulus*, our native and perennial species. There is no lack of climbing vegetation of the best for window gardening of this kind. Clematises of many kinds, Ivy of the large and small leaved forms, Virginian Creepers, Tropaeolums, and Jasmines of varied sorts and exquisite perfume. One of the nicest things for draping large windows at a considerable height from the ground is Veitch's Japan Creeper (*Ampelopsis tricuspidata*). At Oxford the windows of some of the cottages and churches are partly covered with its elegant leaves.—F. B.

4198.—Plants for a window.—Several good articles have appeared recently upon this subject in GARDENING. You do not say what kind of plants you require, and the season is fast passing a way for filling window-boxes. Still, you must make the best of the short season that remains. First of all, you are wanting really permanent things. You cannot do better than make a selection of small shrubs, such as the finer kinds of *Euonymus*, the variegated varieties in particular, which will make a pleasing show during the winter months, putting in autumn between them a few bulbs, such as Crocuses, Tulips, Snowdrops, and such things. These will look well in the spring in contrast to the leaves of the shrubs. You require possibly, however, an effect with flowers as soon as possible, and I cannot advise you more than I have already done a few weeks ago. Zonal Pelargoniums could be used in all the windows, having for an edging the Ivy-leaved kinds, which will hang over and make a charming finish to the box, these in the autumn being substituted by somewhat things as the Ivy, when the dwarf shrubs take the place of the other plants. Take care to have good drainage in the bottom of the boxes, and unless this is given you will not do much good. Then get a good soil, another important point, and as is used for potting, leaving sufficient space at the top to give a liberal allowance of water. The reason why window plants wear too often an unhealthy aspect is because they are too dry at the roots. Remember that in windows they are exposed to the sun and wind, and there is not much soil for the roots. It is too late to get the Canary Creeper now, unless you can purchase large plants, which is not very likely, but you can make good use of *Lobelia* and *Fuchsia*, having one window filled with Zonal Pelargoniums, another with *Fuchsias*, and at this late season fill the other with the White

Marguerite, which is much used for the purpose. The other could be a mixture. I simply name now common things that can be got at once to make a show before the summer and autumn have left us. When the beauty of the plants are past, resort to the shrubs, not forgetting the bulbs. Not half sufficient use is made of bulbous flowers for this purpose. Every garden could be a picture of colour in the spring with their help, and the initial expense is trifling. One of the most charming window gardens I ever saw was made of the *Chionodoxa Lucilia*, commonly called the Glory of the Snow, mixed with dwarf *Narcissus*. Such effects are a relief from the monotony of the usual things seen in windows. You ask for information also regarding the management of window plants? All the plants named to be used at once require comparatively little attention. The great thing is to keep them properly watered, so the soil in the boxes soon gets dry. Remove carefully all decaying leaves, and if hard-leaved plants, such as *Aepidietras*, *Palms*, or *Aralias* are used be careful to keep the foliage sponged occasionally to prevent accumulation of dust. If the windows are near to the road, it will be most important to see to this matter. I may mention that *Aralia Sieboldi* is useful in a window. It has bold, glossy-green leafage, and

entirely devoted to the plants or inhabited, and the plants used only as a decoration? Also whether there is any means of warming the room in winter? If quite without warmth, hardy plants only and the above bulbs could be grown. British Ferns (which are many of them very beautiful) would do well here, and *Carnations*, *Gladioli*, *Wallflower*, *Canterbury Bell*, &c., might be tried; but all these are best out-of-doors, except during their flowering time and in very severe frost or snow. With a fire, so that frost can be excluded, there are a great many room plants that could be grown here—*Palms*, *Aspidistra lurida*, and *Ficus elastica* (*India-rubber-plant*) being some of the handsomest in the way of foliage. These all need to have their broad leaves regularly sponged from dust, and watering should be done only when needed—i.e., when the surface soil is too dry to soil the finger, and then thoroughly emptying their saucers half an hour after watering. All room plants need more water during their season of growth, and less when at rest. A hard and fast rule, such as watering them twice a week, or every day, is therefore a mistake, careful attention to their actual needs being far better. Few flowering plants do well in a west aspect, few morning sun is so necessary for them; but *Fuchsias*, *Musk*, *Mimulus*, and *Primulas* will do fairly well, and any plant which has already set its buds in a sunny situation will open them here and continue to bloom for some time during summer.—I. L. R.

A window garden of climbing plants.

WINTER-FLOWERING ZONAL PELARGONIUMS FOR A ROOM.

ALMOST everyone who takes any interest in flowers possesses a few "Geraniums" (*Zonal Pelargoniums*), and these are so easily grown, blossoming throughout the summer, that they are universal favourites. But the possibility of having their bright blooms in winter is not always thought of, and yet there is no reason why this should not be the case if the plants are managed with this view in summer, and they can be given a sunny window in a warm sitting-room during the winter months. Young plants obtained in small pots at the present time, having been rooted this spring, should be shifted into 4-inch or 5-inch pots, with a good compost of turfy loam and leaf-mould, and a little sand. The potting must be firm, the soil being rammed down rather tightly, and sufficient room left at the top for plentiful watering. The "Geraniums" must stand out of doors all the summer, exposed to the full sunshine, with plenty of air; but it is well to shelter the pots in some way from the effects of the heat, which is apt to destroy the tender roots which cling to the earthenware. This can be done by sinking the pots to the rim in a bed of fine ashes, or placing them "pot thick"—i.e., so near together that they shelter each other, with a board, or a mulch of Cocoa-nut-fibre in front of the first row of pots; but the plants must never be so crowded as to touch each other, for the great object is to make them sturdy and strong, with well-ripened wood and bushy in shape. The points of the shoots must therefore be pinched out once or twice during the summer, and every bud removed as soon as it appears, thus storing up the strength of the plant and its flowering properties for winter work. In August the little plants may be given a slight shift into the next sized pot, with richer soil, in which there is a little old hot-bed stuff, mixed with turfy loam and leaf-mould; and again the potting must be extremely firm, with good drainage and plenty of space for watering. Having been relieved of their buds and pinched back a little (for the last time) a week before the last potting, all the growth they now make may be left intact, and by the end of September the plants should be covered with buds. Lifted into a warm room then with a sunny window they should bloom for months; but this, of course, depends upon the amount of warmth they receive. In any case they will be beautiful objects during the dull autumn days, only requiring a regular supply of water to open a mass of bloom. As they prefer a somewhat dry atmosphere in winter they do not suffer from the fire-heat of a sitting-room as much as most plants, but they will not stand gas, drooping their blooms at once if subjected to its poisonous breath.—I. L. R.

is comparatively tough. Great care should be taken not to overwater.—C. T.
— If you stand the plants in the open not later than the end of September, the growth made in the window will have time to get hardened before winter. You may then plunge the pots to their rims in a border near to a warm wall, and leave them there all winter. Under this treatment you will find them to flower more freely than if you kept them in the house all that time. You may, of course, keep them altogether in the window. If you do so, keep them as cool as you can, and the soil about the roots regularly moist.—J. C. C.
4227.—Plants in a bedroom.—This room, with a due west aspect, would be a good place for many plants during the summer; but in the winter there will be very little sunshine. Bulbs, however, of many kinds would do well and give little trouble. Most of them should be put in during September—i.e., *Hyalocynthos*, *Crocuses*, *Snowdrops*, *Tulips*, *Narcissus*, and the lovely little sky-blue *Scilla sibirica*. All these are best out-of-doors after being potted, standing on a thick bed of ashes, and covered with an inch or two of the same, until the frost sets in during October; then they can be brought indoors and placed in the window, giving them all the light possible in mild weather. "M. B. C." does not say whether the bedroom window is to be

MARKET FLOWERS.

FREQUENT enquiries are made as to what kinds of flowers are likely to yield a profit if grown for sale, but without a knowledge of each separate case it would be impossible to give anything like an accurate answer, as much depends on the locality. But, taking the average, I should say that the following brief list may be relied upon as likely to return the grower fair profits for labour and capital invested. I refer only to such as can be grown to perfection in the open air.

CARNATIONS and CLOVES are in great demand, and, given a suitable soil, naturally well drained, they are very free. If care is taken to layer all the strongest shoots in a sharp, gritty soil, there is little difficulty in keeping up a supply of plants. The layers should be put down at once and taken off as soon as well rooted, and planted in beds, so that they may get established before frost sets in. There is a ready sale for Carnation blooms, and especially for the dark-crimson Cloves.

CHRYSANTHEMUMS are extremely popular as out flowers, not only for the great variety and beauty of their blooms, but especially from the fact of their coming in at a time when other flowers are on the wane; but for blooming out-of-doors the latest varieties must be avoided. After October the frost is frequently too severe to allow of their expanding. The season commences with Mme. Desgrange kinds, and follows on with all the popular early-flowering varieties. They are of easy culture.

DAHLIAS, although not nearly so popular as a few years back, are still in request in autumn. I find the Cactus varieties, Pompon and singles, the best for cutting, especially the white and scarlet varieties.

LILIUM CANDIDUM, the common White Lily, is a very popular flower, and where the soil is suitable—namely, light and well drained, it will be found profitable to grow. I transplant about every fourth year, and get the finest spikes about the second and third years after moving; but after the bulbs increase, the spikes, although more numerous, get smaller. They sell best before they are fully expanded.

LILY OF THE VALLEY always soils well, and well-established beds out-of-doors are by no means unsatisfactory. I lift a quantity of crowns for forcing during the winter, and after plucking out all the largest flowering crowns, the smaller ones are again planted in beds for a couple of years' growth, so that I always have plenty of crowns for forcing and beds for gathering.

LAVENDER.—This is one of those good old garden flowers that retain their popularity through all changes. It is of easy culture, striking root freely from good, large pieces planted firmly in the soil in autumn, and a bed once established lasts for a good many years. The crop is cut when the heads are in full bloom, and sells readily, either to private houses or to distillers of perfumes.

MARQUETTES have of late years been in great request, and, either white or yellow, planted out in May will continue to bloom profusely

until outdoor flowers are over. Tied in bunches, they sell freely to florists or flower-hawkers.

PINKS.—The old-fashioned fringed Pinke are very free-blooming, and if old clumps are divided and replanted at this time of year they will produce a fine crop of flowers next season. Mrs. Sinkins is an excellent acquisition.

ROSES are unquestionably the safest flower to grow in quantity for market, as there is always a demand for them. The price obtainable is now very low, if compared with that of a few years back; but this affects their growth more under glass than in the open, and anyone going in for market flowers must certainly make Hybrid Perpetuals and other hardy Roses that keep on blooming for a long period one of their strongest points. Such kinds as Souvenir de la Malmaison that flower best in autumn are very valuable.

SWEET PEAS find a ready sale, especially if sown in autumn and got in to flower early in May. The distinct colours are best.

SWEET SULTAN is one of the best annuals to grow for cutting (yellow, white, and purple). It has long stalks. Sow early and thin out.

STOCKS of nearly all kinds are favourite flowers and sell readily. The old Brompton is one of the first to make a good display of colour, and during summer the Tea-wink, Queen, and Mid-Lethian are very free.

WALLFLOWERS are grown in quantity in the vicinity of large towns, and are of the easiest culture. The seed is sown very early in spring, and as soon as the plants are large enough they are dibbled out in rows, generally between fruit-trees, where they get a little shelter, as they commence to flower during winter, and very early in spring they are tied in bunches and sent to market.

VIOLETS of the Single Blue Czar kind are grown by acres in the South of England, and few flowers any better if the winter proves mild. They find a ready sale. J. GROOM, Gosport.

GLADIOLI.—The Gladioli is becoming a popular flower in gardens, and M. Lemoine has raised some good hardy kinds named Lemoinei. He has given his name to this section which is peculiarly adapted for gardens by reason of their hardiness, although the flowers are not so brilliant as those of the Nanceianus type. This is the result of hybridizing, and amongst the various kinds are those of brilliant colours, such as President Carnot, orimeon, with creamy-white centre. As yet the forms are somewhat expensive, but will get cheaper in time. These hybrid forms seem to succeed much better in the garden than the varieties of gandavensis, but there is a tendency to get coarse, big flowers which are not necessarily the more showy. Those that are smaller, neater, and produced in greater abundance are more satisfactory. A very fine Gladioli is bronchleyensis. It is an old favourite, but very free, and not difficult to grow, whilst the tall spikes of orimeon, or rather scarlet, flowers make a great display in the garden.—V. C.

1894.—A tenant's fixture greenhouse.—Yes, you can grow a course of loose brooks for the purpose of rest upon without prejudice to the removable when necessary.—B. C. R.

REMEDIES FOR INSECT PESTS.

NEVER allow any weeds to grow on the beds, as insects which feed on them may spread to the crops, and the weeds may provide food for insects when the ground is fallow or in corners and waste places, or under hedges, as insects are fond of such positions for breeding in. Rubbish, stones, and the refuse of a crop should never be allowed to lie about, as they form a welcome shelter for all kinds of pests. A proper rotation of crops is most beneficial. If a crop is attacked by a certain insect it should be followed by one which is not liable to be injured by the same pest. Many plants suffer most from the attacks of insects when they are quite young; in such cases the plants should be pushed into vigorous growth by judicious cultivation as soon as possible. Birds should be encouraged in gardens. Few persons realise what an enormous number of insects are destroyed by birds, particularly during the breeding season, when nearly all young birds are fed on animal food. Ripe fruit and fruit-buds, however, must often be protected from them. When the leaves have fallen in the autumn all those under fruit-trees and hedges should be collected and burnt, as all kinds of pests harbour under them. Any leaves which did not fall with the others should be picked off, as there are often chrysalides curled up in them. In the course of the winter the ground under fruit-trees should be broken up so as to expose to the elements and the birds any insects or chrysalides which may be wintering there. A sharp look-out should be kept when any digging is going on for chrysalides or cocoons. As soon as any insect attack is noticed, steps should be immediately taken to check it, as at this time the old proverb "a stitch in time saves nine" is especially true, particularly when aphides are the foes. Keep any ground which is not in use well hoed; this will kill any weeds and expose any insects which may be in the soil. In greenhouses be very careful in introducing a fresh plant, whether obtained from a friend or a nurseryman, to ascertain that it is free from aphides, scale, mealy-bug, thrips, &c., as otherwise a house which was perfectly free from insects may soon become just the reverse. Give plants as much ventilation as possible consistent with maintaining a proper temperature, for in their natural state they are always in the open air. If fumigation or washing has to be resorted to, do not be content with one application, but repeat it in three or four days' time, so that any eggs which may not have been killed by the first attempt may succumb to the second. If ants be found running over plants, it is an almost certain sign that the latter are attacked by aphides or scale insects, which the ants are searching for to obtain the sweet substance they exude. As soon as any holes are found in the mortar of the walls inside a greenhouse or any cracks in which insects may shelter, the walls should be replastered. G.

1893.—Destroying wireworms.—Try a dressing of tan-bushings of gas-lime spread equally over the land. Dig it in, leaving the surface rough till spring. Fork the land over again then, and plant with Potatoes or other vegetables.—E. H.

TREES & SHRUBS.

THE VENETIAN SUMACH.

THIS is a striking shrub when in flower, and its profuse blooming has gained for it the name of Wig-tree, or Smoke-plant, the effect of its feathery, sterile flower-clusters angaggesting a film of smoke, as seen from a distance. Our illustration shows well its beauty as an isolated specimen, permitted to develop itself without hindrance from neighbouring things. Under these conditions one sees the *Rhus cotinus*, as it is called botanically, in its best aspect. The shrub is pleasing when the garden is getting somewhat dull, and although it is not a tall grower, it spreads about, making a dense, bushy, and vigorous growth. The leaves are glaucous colour, round in shape, and although the flowers themselves are inconspicuous, there is much beauty in the feathery reddish-purple clusters that succeed them. They remain attractive over a comparatively long season. The Smoke-plant was introduced from Southern Europe as long ago as 1656. It is quite hardy, and most pleasing when permitted to develop without being crowded up by other shrubs, as is too often the case in gardens. It is interesting to mention that M. Ed. Andre, writing in the *Revue Horticole*, describes the Venetian Sumach in its native home. He says: "In the well-known mountain-park of the 'Portes de fer,' between Orseva and Turn-Severin, where the Danube has cut a channel through the lofty Transylvanian ranges, a sight worth seeing in the month of October is that of the Venetian Sumachs, which carpet the slopes, when their foliage is lighted up by the rays of the setting sun, affording a singular contrast to the white foliage of the silvery-leaved Lime-tree."

Spiraea paniculata.—Though differences of opinion may exist as to the correctness of the name given, there can be none as to its being a very beautiful *Spiraea*, and one, too, that blooms later than many of the others. The flowers are borne in erect branching panicles, which are usually more or less pyramidal in shape, and its season of blooming is extended by the fact that the flowers on the secondary branches do not expand till the central ones have been open some time. A large bush of it some 5 feet or 6 feet high is, when occupying an isolated position and in full flower, a very beautiful object.—H.

4338.—**Ash-tree.**—The unusual number of seeds the tree is carrying, and the long drought, are no doubt the cause of its weak condition. It would relieve the tree immensely if you remove the seeds at once. It might not make any fresh growth this season, but the taking away of such a heavy load will give it a longer time to recover its strength and enable it to start away more vigorously next year. The Ash likes a moist position. Probably yours is rather dry.—J. C. C.

4330.—**Myrtle cuttings.**—Cuttings of the nearly mature wood—that about two-thirds ripe is the best of the current season—may be inserted in September or October, in well-drained pots of sandy loam, mixed with a little leaf-mould. If kept in a "quiet" corner of the greenhouse, away from sun and draughts, and the soil maintained in a half moist condition, most of them will be found to have formed roots, and will begin to grow in the spring. Another way is to take off the young growths—side shoots, or tops—in the spring, when about 2 inches long, and insert them thickly in pots of very sandy soil, as before. If these are placed in a warm, close house or pit, or in a frame with gentle bottom-heat, and kept regularly moist and shaded, they will root with great certainty, and make nice little plants the same season. A frame will do for cuttings inserted in the autumn as well as a house, provided that frost can be excluded, and I have also rooted them in the window of a moderately warm room.—B. C. R.

When the wood is about three parts ripened is the best time to take cuttings of these plants. Any sandy leaf-soil will do. Make them firm, and do not use too large a cutting. If kept close in a frame or greenhouse until called, and then placed in a gentle bottom-heat, the sweet-smelling shrub is propagated with ease.—F. H.

Myrtle shoots just getting firm, taken with a piece of last year's wood, if put in now will root during the winter and be ready for potting off in spring. Plant firmly in sandy soil; keep in the frame till end of October, then

move to greenhouse. Keep close, and shade from hot sun-bles. A bell-glass will be useful, but the inside of the glass must be wiped dry every morning.—F. H.

—The proper time to put in Myrtle cuttings is when the young wood is fully grown, about August. Take the cuttings off at a joint, and plant about half-a-dozen in a 4 inch or 5-inch flower-pot. The compost should be formed of loam, leaf-mould, peat-soil, and sand in equal proportions. Plant the cuttings firmly round the sides of the flower-pots, and place them under a close hand-light; or if there be only one flower-pot full of cuttings, a bell-glass would be more convenient; put the small pot containing them inside a larger one, and fill up the space between with coarse sand or fine gravel. The rim of the bell-glass should rest on the sand between the two pots, and this keeps the air well away from the cuttings. The bell-glass should be removed daily, wiping the inside round with a dry cloth. They will take six weeks or two months to form roots, and when they have started to grow, repot them singly.

The Venetian Sumach (*Rhus cotinus*).

Good soil for Myrtles is yellow loam, two parts: one part light fibrous peat; and one part leaf-mould, with a little sand added.—J. D. E.

4329.—**Thuja Lobbi for a hedge.**—This is an excellent shrub for a hedge in a windy situation, but I fear it is rather too hungry a feeder and too gross a grower to be near flower-beds. You could cut it as freely as any hedge, and regulate its height from 3 feet up to 12 feet or 14 feet. I would prefer the American *Arbor-vitæ* as being closer in habit and of steadier growth. The distance apart must depend in a measure upon the height you wish your future hedge to be.—P. U.

4303.—**Treatment of an Araucaria.**—A good remedy would be a top-dressing of loam, kept away from the stem of the tree. Do the work carefully, but I am afraid there is no real remedy. The *Araucaria* requires an open spot, not cramped up as it usually is in gardens. It is curious that such a tree should be planted so freely in places for which it is not fitted. More than half the examples we see die away in the manner described by you, and the only remedy is, I fear, to remove the tree to more congenial quarters. Once it has got in bad condition it is not an easy matter to restore it. In nine cases out of ten it is impossible.—C. T.

Do not complain the tree mentioned by "Pipe" is suffering from starvation, and the remedy is feeding. Dig a trench 18 inches wide

and 2 feet deep right round the tree at 4 feet distance from the trunk, and into the trench put a load of good stable-manure; tread down, and fill in the trench with the best soil obtainable. I had two fine young trees similarly afflicted, but under the above treatment the loss of sap is stayed and the downward progress averted. If allowed to go on the end is certain death.—H. K. FITCHCOCK, M.D., *Bournemouth*.

Best twelve Daffodils.—One of the most useful bulbs is the Daffodil, or Narcissus, as it is also called. The lists of bulbs are so bewildering that it is an assistance to those who require simply a few kinds to choose about a dozen of the best. Of Daffodils a good selection would be *Horsfieldi* or *Empress*, the latter preferably, although some appreciate the former more than the other. It is a trumpet variety, the flowers very large, and with a creamy-white perianth, whilst the trumpet is rich-yellow. It is one of the finest of the family. *Empress* blooms a little later, and the two kinds might thus be planted to form a succession. *Maximus* is a good type, but not so strong as those mentioned. Its flowers are, however, very beautiful, intense yellow, bold, and of splendid shape. *Emperor* is another fine variety, yellow, and strong in growth. *Glory of Leyden* is, I fear, rather too expensive for the majority, but it is a noble Daffodil, large and robust. It will be much grown in the future. Of the *incomparabilis* section choose the fine *Sir Watkin*, which, if it varies in different gardens, is always pleasing to look at for the shades of yellow in the large flowers. The early-flowering *Santa Maria*, the flowers intense yellow, is a good kind. I think it is one of the most beautiful of all Daffodils, and certainly the richest in colour. *Ar-Righ* is a good Trumpet kind, the flowers rich yellow and the growth robust. *Princeps* blooms early, and is a worthy kind. One may select either this or *Golden Sprig*, which is a very rich yellow. Of the *Poet's* varieties *ornatus* is very beautiful, early, and free, then one must also have the double white, appropriately likened to a *Cardenia*. Of the *Hoop-petticoot* forms *Corchularia citrina* is one of the more vigorous, and forms a good edging; and of the doubles select the old *Double Telamonius* and the handsome *Butter-and-Eggs* variety. In gardens of average size the more troublesome kinds, such as *N. cyclamineus*, should be avoided. *N. nans* or *N. minor* are worth a note for their beauty as dwarf kinds, each smothered with flowers. *Stella* is a beautiful kind; also *N. Barri* conspicuous, in which the cup is stained with rich orange.—V. C.

The Purple Cornflower.—A splendid hardy plant blooming in August is the Purple Cornflower, known botanically as *Rudbeckia purpurea*. It grows strongly, and will exceed even near large towns, making a fine leafy clump, vigorous, and in every way satisfactory. Amateurs do not seem to know much of it, but it is worth a note, whilst the flowers are very distinct in colour, bold in shape, and purple-rose, set off by a blackish centre. At this season of the year there is a surfeit of yellow from the Perennial Sunflowers and other composites, so that the rosy-purple shade of this *Rudbeckia* is a decided relief and contrast to that of flowers in general. It is perfectly hardy, and a good piece put in in the autumn will make a show next year.—V. C.

Lilium superbum.—This is a lovely Lily. It is in full bloom in July, and the fortunate owner of a large garden cannot let in many a charming and picturesque way. It is a tall grower, the slender spikes rising over 8 feet in height, and when the groundwork is Rhododendrons, the young shoots are protected in spring from frosts. The flowers are borne in large numbers on the stems, and vary greatly in colour, the most brilliant being those of a bright scarlet, or rather, I should write, crimson, like a Game of fire seen from a distance in the woodland. It is not everyone, of course, that has a woodland, but a good colony of this species, sending up its tall stems, makes a fine picture. Unlike many others, it makes a vigorous growth, is perfectly at home in a light, peaty soil, and has an irresistible beauty when swaying about in the wind on a summer day. The name is certainly appropriate. *L. superbum* is for the large garden. *L. superbum* is lost in cramped places.—C. T.

ROSES.

THE PLEASURE OF ROSE-GROWING.

It is not a difficult matter to decide by what means we may obtain the greatest amount of pleasure from our Roses. Some seek it through the medium of the exhibition, but there it is dearly bought—at least, by amateurs. Our methods of Rose showing are so stereotyped, we think so much of single blooms, that if one would enter the show arena he must begin by making great sacrifices. The pleasure of Rose showing does not permanently satisfy. Anyone visiting a Rose show cannot fail to admire the magnificent flowers seen there. I do not wish to say one word against the practice of growing and showing them. It is something to know to what perfection of form and colouring particular kinds can be brought, but that is not, or should not be, the sole end and aim of Rose shows. A celebrated amateur exhibitor recently visited a garden where Roses are largely grown solely for effect, and he confessed that that was more after his own desire, and he thought he should give up exhibiting. In the course of that ramble he experienced pleasure altogether beyond what he had realised as an exhibitor. To exhibit successfully one must practise numerous details that need never worry the ordinary grower. From the pruning to the flowering there is a marked difference in the methods. The

EXHIBITOR'S PLANTS must be hard pruned, and then comes the inevitable disbudding. It is no exaggeration to state in regard to many Roses that the ordinary grower has a score of flowers where the exhibitor can take but one. When the buds are selected then comes the feeding. Then there is the question of protecting and shading from storm or bright sunshine. Yet this is essential to meet the requirements of the exhibition, which at present only fosters the production of fine flowers, and therefore excludes many worthy kinds simply because their flowers are not up to a particular standard of form. If we would seek and realise the fullest pleasure, we must wait until at Rose shows classes are provided for Roses as grown in gardens, the same to be judged on their own merits, and not from any pre-existing standard. At present one type of flower only is encouraged or accepted, regardless of those lovely kinds so handsome in the bud and so profuse in regard to the great trusses of flowers they produce. In the garden these last often give us the most pleasure. The exhibitor above referred to was alarmed with Mme. Joseph Schwartz as it appeared in a group, the strong shoots terminated by immense clusters of bloom standing erect, some of the flowers fully out, showing their great flesh-tinted, rose-margined, shell-like petals, others mere buds of delicate hue opening in succession. Marquise de Vivens and Dr. Grill were unknown to him, and yet there were not two lovelier groups, especially that of the latter. Such kinds as these never appear at the shows, but why should they not do so? If such kinds treated as the show kinds are will not then produce full flowers simply because naturally there is not sufficient substance, surely they should not be ignored. Whether exhibited or not they will give us much pleasure in gardens, as they are most reliable in regard to their blooming. If the bud of to-day is a full-blown flower to-morrow, that matters not, for quantity atones for want of quality, and even these many-tinted, open, loose flowers have a fine effect on a bright summer day. Again, when we grow for pleasure only we shall not have many leggy standards, but dwarf bush plants, and these not set out a yard apart, but grouped or massed, since this is the very best way of showing off the merits of fine Roses. It is too generally supposed that

GROSS FEEDERS, and the heavy manurial mulches and the drenchings with strong liquid so commonly given detract from our pleasure. We can modify this to a considerable extent, and have Roses in abundance without the slightest aid from rank manures. If our Rose beds are redolent with the odours of the farm-yard, we cannot have them beside our open doors or beneath our windows, and, other things being favourable, that is just the spot where at the present time we should have great glowing groups of Tea and Monthly Roses filling the air with rich fragrances. Many Roses make such excellent bushes, that when grouped and

in full growth they effectually hide the earth beneath them. Those that do not do so, and newly-planted groups also, should be carpeted with some of the many dwarf plants so suitable for the purpose. This adds to their appearance and increases our pleasure. Surface-rooting plants, like Sedum and Saxifrage, and lovely alpines, such as *Linaria alpina*, do not rob the Roses in the slightest degree, but without a doubt they benefit them, for on a scorching hot day (June 28th) I was admiring a group of The Bride Tea Rose, carpeted with *Sedum glaucum*, and placing my hand under and among the carpet, I found the earth cool and moist, whilst bare ground was hot and dry. That night there came the most severe thunderstorm, accompanied by a deluge of rain, that has been in this district for years. Next morning I looked round the Roses, and the full, heavy flowers of this and other kinds were borne down by the weight of water that had descended upon them, but they were pure and unsoiled, for the advantages of the carpet were shown in that no splashing of the earth could take place. A great many are thinking what they can plant to reduce the quantity of tender bedding plants. If they have sunny flower gardens let them try Tea Roses, for they are ever growing, ever blooming, are a source of great pleasure through summer and autumn, can be planted thickly alone or thinly to admit of combinations, and, all things considered, are the most thoroughly satisfactory of all. H.

ROSES BY THE SEA.

HAVING for some years been engaged in the cultivation of Roses in the neighbourhood of the sea leads me to give my views as to the best kinds for growing there. Situations even by the sea vary greatly, and Roses may succeed splendidly and also fail in the same district, and yet only be separated a few yards. Visitors to the seaside may notice a variety growing and blooming splendidly, and there and then come to the conclusion that the variety is specially adapted for the purpose, and recommend it in print accordingly. They may have overlooked the special conditions under which it is growing. Perhaps it might have been situated in an alcove or protected by a hutch, and which makes all the difference between success and failure. Given the requisite shelter, Roses may be grown as successfully near the sea as further inland, and, in the case of Teas, perhaps better. In fact, as far as these letters are concerned, the beautiful tints are more pronounced and certainly much better than any I have ever seen on flowers inland. No doubt most people are aware it is difficult for almost any kind of tree or shrub to grow within swoop of the sea spray, and when subjected to ontling draughts, as is very often the case, it is almost death. Roses are no more exempt than anything else, for though they may look thriving enough one day, if a rough storm comes the young growths would literally be soon lashed to pieces. From my experience thus gained, I came to the conclusion that if Roses are to thrive well near the sea it is absolutely necessary that shelter be provided. No doubt there may be found here and there a few natural coves where Roses thrive surprisingly well, but these are exceptions. A low wall often makes all the difference between success and failure, and from such a wall I have gathered the loveliest of Teas, and also in the narrow border in front. From the above it will be gathered that there is no hard-and-fast rule to go by as far as special varieties are concerned, except that the Teas, Noisettes, and Chinas thrive the most satisfactorily when given the needful shelter. The darker Hybrid Perpetuals are certainly the least satisfactory, but I have gathered splendid blooms even of these if a favourable time happened to attend the opening of the buds. For the benefit of seaside readers I will give a list of the Teas and some other kinds which used to thrive exceedingly well. Anna Gilliver, Catherine Mermet, Gloire de Dijon, Homère, Mme. Berard, Mme. Bravy, Mme. Chedene Guinoisseau, Mme. de St. Joseph, Marie van Houtte, Mme. Lambert, Rubens, Souvenir d'un Ami, and William Allen Richardson. The China Roses and the varieties of Rosa Polyantha also do well. Of this latter section Mills. Cecile Brunner was of splendid kind, large clusters of small flowers forming very frooly. Where the Dog Rose

and Blackberry thrive, there, too, will Roses grow when given the ordinary cultural attention, with the necessary shelter from very rough winds and direct spray. Y.

ROSE NOTES.

AUGUST is not a month of many blooms, but a season of second growth, a preparation for the autumnal display. It is desirable to have the Teas where we can see them day by day, and, on the other hand, it is better to have the Hybrid Perpetuals where they will not too plainly shroud their nakedness, for really the season of their beauty, whether of leaf or flower, is a short one, often reaching its limit before summer is past. It is very different with the Teas, as they are delightful when growing vigorously, the varied tints of leaf and shoot embracing shades that contrast prettily with the rich dark green of the previous and mature growth. In summer dwarf plants send up from the ground fine strong shoots which terminate in a great branched cluster of flowers, and these have an additional value, for if they ripen and stand the winter we can rejuvenate the bushes by cutting old growth clean away and retaining the young and vigorous wood. Among the kinds that have been sending up such shoots is Marie van Houtte on its new roots. This removes a doubt that hitherto I had entertained, namely, whether after all the vigorous root-action of the season, that is the seedling Brier, was not the source of the vigour that has been manifested by all our best Teas. For two seasons I have watched this group and been disappointed, for though the plants were healthy and flowered, they kept very dwarf and the wood they made was slender. Now, however, each plant has doubled its height and strength by sending up one or more shoots, thick, strong, and nearly a yard in height. This would seem to prove that when once the plants have made strong roots they will compare favourably with those upon foster roots. If we raise plants from cuttings, there is a reluctance of growth above ground and below. The quickest method is not necessarily the best, and if that is all we gain, the saving of time is practically of little moment. Though we have to wait a little longer, it is better to establish our best Roses on their own roots; then they will not be easily destroyed, for if an unkind winter levels them to the ground, they will shoot from beneath and grow and flower freely. Ernest Metz has been fine this year. It is undoubtedly one of the great Tea Roses of the future. From now onward, with fine weather, there is much enjoyment among the Roses. The days are shorter and cooler, caterpillars are gone, fly ceases to be a trouble, the ravages of mildew are checked, the flowers open gradually and last longer in perfection. The flowers may not be quite so fine, but they are pretty and always sweetly scented. H.

4197.—Flower-pots becoming green.

—No, the plants will not suffer, but it is unsightly, and usually occurs when much water has been used or the pots have remained long in one place without being cleaned. Perhaps the pots were dirty when used. It is not uncommon to see an antonra especially using dirty pots, but they should be always clean. This is a golden rule. I should take the pots out of the frame or wherever they are, and give them a thorough good scrubbing with a hard brush and cold water. No harm will happen to the plants if the operation is done with reasonable care.—C. T.

Gentiana asclepiadea.—At the end of summer one of the finest hardy plants in bloom is this Gentian. It is superb when one sees a large mass of it, and many readers of GARDENING can grow this handsome plant. It likes moisture and a certain amount of shade, whilst the soil must be moderately rich. A position on the rockery, where the situation is damp and not too exposed, suits it admirably, the long stems being studded with rich blue flowers throughout their length, and they make a decided contrast against those of the variety alba. There is considerable diversity of colouring in the flowers—some self blue, others with white markings. It ripens seed freely, and is raised best in this way, as seedling and stronger than divided pieces. Sow the seed in a pot plainly and keep in a cold frame. Be careful to water judiciously.—V. C.

THE KITCHEN GARDEN.

CULTURE OF ENDIVE.

WELL-GROWN and thoroughly blanched Endive is only slightly inferior to Lettuce in point of crispness and flavour, and as far as appearance is concerned—a very important consideration too—it surpasses it any time after the end of September. It is doubtful, however, if the

Moss Curled Endive (one-eighth natural size).

value of a good supply of Endive is fully appreciated by either amateur gardeners or the proprietors of comparatively small gardens, or otherwise very much more of it would be grown. To a certain extent, the taste for Endive has to be acquired, especially when it is served whole and without any dressing; but the slightly bitter taste accompanying it is pleasing to many palates. The most valuable crops, as a rule, are those obtained from plants raised in July and the early part of August, these being the least liable to run to seed prematurely, and arriving at a serviceable size when Lettuces are less abundant. If the plants fail to grow strongly after being put out, it is most probably owing to the ground being either too poor or too cold and heavy. The finest Endive in the most easily produced on freely-manured light soils, there being no better sites than those cleared of early Potatoes, and extra fine produce can be obtained between the rows of newly-planted Asparagus. Unfortunately, the more strongly they are grown the more liable are the plants to be spoiled by frosts. Quite small plants, or, say, any obtained by sowing seed in August or the early part of September, if put out rather thickly on a warm raised border, will usually withstand very severe frosts, and if covered with frames when these can be spared, the growth through the winter will go on steadily, a serviceable lot of hearts being available in February, March, and April for mixing with the earliest Lettuce. Many succeed in growing a capital lot of Endive only to spoil the greater portion either by blanching too much at one time, or because they have neglected to store the bulk of the crop where it is out of the reach of severe frosts. It should be remembered that the blanching process effectually stops the growth of the plants, and should not, therefore, be commenced too soon; also that Endive keeps badly after it is blanched, thus rendering it imperative that the process be piecemeal rather than wholesale. When it is known in addition how quickly the plants decay after the tips of the leaves have been crippled by frosts and other causes, it will be more fully realized how much care and judgment are needed to preserve and prepare the crops for use during the late autumn and winter months. In some seasons the plants left in the open escape injury as late as the end of November, but I hold that the bulk of the crop should be stored or attended to in some way much earlier, or, say, by the middle of October, and the most forward plants either protected where they are, or transplanted to frames by the end of September. It is in the low-lying districts where the greatest difficulty is experienced in preserving Endive, a very moderate frost damaging the plants sometimes in September. The safest course in all such localities is to grow the Endive in beds as

much as possible, these at the present time being enclosed by frames and covered by lights or mats whenever frosts are imminent.

MOSS CURLED, a variety of compact growth, is sometimes grown for the earliest supplies, but it is very tender, and ought not to be much relied upon. **Green Curled**, of which there are two or more forms, all more or less distinct and serviceable, can be had fit for use quite as soon as Endive is required in most establishments. The French selection, **Lonviers** fine lacinated, is of sturdy growth, and promises to be of superior quality, but I have not yet had an opportunity of testing its keeping qualities. **Picpa Fine Curled** is a reliable form of Green Curled, and is planted extensively here. For use when Lettuce is not available, and also for cooking purposes, there is none to surpass a good stock of the **Batavian Broad-leaved**, this also varying considerably. What is known as the **Improved Form**, when it can be obtained true, is undoubtedly the best, but not infrequently quite another thing is supplied by seedsmen. The **Lettuce-leaved Batavian** (*Scerole hionde*) is a favourite variety in France, and this we are trying for the first time. It is of rather ragged growth, and in all probability will not prove so hardy and useful as the **Batavian Broad-leaved Improved**. All will be treated alike as regards protection and blanching, nothing being left to chance. Early in October a considerable number of frames, span-roofed and otherwise, will be at liberty for protecting salad. Some will be placed directly over the Endive where grown, and completely filled if need be by transplanting the requisite number from other quarters. Others will be set on a dry warm border, and eventually closely filled with both **Green Curled** and **Broad-leaved** forms, these being fully grown and previously tied up to facilitate the process of moving them with a good ball of soil about the roots. When lifted carefully and before frosts have injured the foliage, Endive will keep surprisingly well in sheds, and where space is limited it may be stored in conical heaps surrounded by dry sand, the points of the leaves being brought up well together so as to protect the hearts facing outwards. The best Endive, and for a greater length of time, can, however, be had by keeping the plants in a healthy growing state in frames or the borders of cool fruit-houses, blanching these as they are required for use.

BLANCHING, as before pointed out, should not be commenced till the plants are nearly or quite fully grown, from thirty to fifty plants, according to circumstances, being prepared at weekly intervals. As long as the plants can safely be left in the open, the blanching can be most simply effected by tying the outer leaves well up together, this excluding the light from the hearts; but if they are enclosed singly in 6-inch or larger pots inverted over them and the holes stopped, the process will be more rapid, and protection will also be afforded. The earliest Endive may be quickly blanched by having either slates, tiles, or thin boards laid on them, and fresh hay is often used for a similar purpose. The most perfect Endive, even, in my opinion, be obtained by placing strong plants in a Mushroom-house or a warm, dark cellar in batches. Here they blanch quickly and beautifully, and are more crisp and sweet than is the case when otherwise prepared for use. We always bed the plants wherever stored under glass in fairly good, moist soil, and keep this moist as much as possible without resorting to overhead watering. Dryness at the roots causes the leaves to become tough, and also induces premature flowering. W.

VENTILATING CUCUMBER-HOUSES.

UNTIL I turned my attention to market growing I was an advocate for free ventilation for Cucumbers, as in a gentleman's garden it is more important to have a regular supply for a considerable period than to cut a great number of Cucumbers early in the season. There is no doubt that Cucumbers can be rushed on with heat and moisture. During the hot days of last June the growth was marvellous; small fruits one day would be large fruits fit to cut the next. I calculate that by the non-ventilating system, with abundance of moisture, about double the quantity of Cucumbers may be cut in the same time from the same space as when they are given. It should be understood, however,

that in market growing large houses are mostly employed, and therefore there is not that sense of stagnation that is present when a small house is kept closed. In a house 100 feet or 200 feet long there is always a certain amount of circulation going on. For Cucumber-growing on the non-ventilating system, I prefer the houses which are span-roofed to run east and west, and then if the south side of the span is shaded with whitening and eize, the plants may have the full light from clear glass on the north side. A house running north and south would require both sides shaded, and this would darken the house so much as to weaken growth, and the plants would sooner succumb to the forcing treatment. Under this system if they are to have any degree of permanency they must have plenty of space. The plants should be not less than 10 feet apart, as the growth after they are well started and on the trellis is exceedingly rapid, and if planted so near as they generally are in private gardens, the knife would always have to be in evidence, and this would be ruinous in effect. What is wanted in Cucumber culture is quick growth, and this the non-ventilating system gives in a very marked manner accompanied by colour and shape. It is just possible that a Cucumber grown so rapidly will not keep fresh so long, but one never hears complaints; perhaps the rapid sale prevents this, and certainly the fruit is beautifully fresh and green. A small house worked on the non-ventilating system would probably be stuffy, but this is not felt in a large house. Everybody has to make the best of the means at his disposal, and it should always be borne in mind that Cucumbers from Easter to Whit-tide are worth at least double what they will be later on, and if the plants give way under the pressure (which if they have room enough they seldom do), even then it pays better to run them out and fill in again with young plants which are usually kept in stock in case of a blank appearing. H.

4335.—**Scabby Potatoes**.—It is not usual for Potatoes to turn out scabby from a loose soil. There is, therefore, something in its composition that causes it. Strong manure is known to promote scab on the tubers if it is used at the time of planting, and especially that from pig-styes. I advise you to change the character of the manure if you use any, and not disturb the ground after it is dug up in the

White Batavian Endive (one-eighth natural size).

winter. Plant the sets with a dibber, as the firmer you can get such ground the more likely you are to secure the tubers free from the defect you mention.—J. O. C.

4321.—**Liquid manure for Tomatoes**.—Healthy, well-rooted plants growing in pots, boxes, or well drained borders cannot have anything better given them than a diluted infusion of either horse or sheep's droppings once or twice a week while the fruit is swelling. Some weak cool water occasionally, say, every other week, will keep the plants in good condition,

and impart a healthy, deep-green hue to the foliage. In the way of a stimulant, a weak solution of either nitrate of soda or sulphate of ammonia, half an ounce to the gallon, is excellent, but must not be given too frequently. These salts greatly stimulate the root action, and a dose or two given shortly before a top-dressing is applied, or as a change from the ordinary liquid-manure, is usually followed by the best results. Many growers use guano to a considerable extent—generally in solution—and some in a large way whom I know say that they find the ichthemic kind superior to any other, at least, for this particular subject.—B. C. R.

I have used a good many kinds of liquid-manure for Tomatoes, and I have, as contrasting treatment, trusted to heavy manuring of stable manure, and used only plain water. The results in the latter case were equal to heat kind of artificial, and cost much less. A load of stable-manure will manure a good many yards of border surface, and the cost would be about 5s. or 6s., and this lasts the whole season. That the plants like this treatment is shown by the rapid way in which the roots work into it. Five shillings spent in artificials would go into a very little way in manuring a large house of Tomatoes.—E. H.

I have used nothing but sewage-water in the way of stimulants for my Tomatoes all the season, varied with an occasional dose of clear water. I have every reason to be satisfied with it. Of course, I have tried chemical manures for them, and if I have a preference for either it is for ammonia in liquid form, given once a week at the rate of half an ounce to one gallon of water. This quantity must not be exceeded, or the flowers will not set properly.—J. C. C.

The Tomato is a very free-rooting plant and a gross feeder. It requires good soil to grow in, in the first place, well enriched with decayed manure and powdered bones, and when cultivated in flower-pots, rich surface-dressings, composed of equal parts of decayed manure and bones, cause greater vigour in the plants than manure-water does; but after the soil is well filled with roots, and the surface-dressing as well, liquid-manure is necessary to maintain a healthy growth and develop the fruits to their full size. There is none better than partly-decayed stable-manure, soaked in water for about twenty-four hours; the liquid by that time will become clear, and of a dark-brown colour; dilute it with about half its bulk, or more, of clear water, and apply this at every alternate watering.—J. D. E.

I do not find it makes any difference what class of liquid-manure is used, but I do find a considerable advantage from using a variety of manures, the change being decidedly beneficial.—F. U.

1331—Artificial manure.—Peat Moss-litter, when it has passed through the stable, is an excellent manure, better for some things than straw-manure, but if sufficient cannot be obtained, horse-dust may be used. Fish-manure I have found excellent for most things, and guano, when it can be obtained, is very good when applied to the surface and hoed in. Nitrate of soda is good for all the Cabbage tribe.—J. D. E.

Peat-Moss-litter can hardly be called manure until it has been used in the stable. When mixed with the droppings of horses and saturated with their urine it is then excellent. I like it better than manures made from straw-litter. I like nitrate of soda for light land, mixed with common salt, 10 lb. of salt to 5 lb. of nitrate, and used just before cropping, or the salt may be used during the cultivating operations in the spring, and the nitrate any time during the growing season in damp weather.—E. H.

The Peat-Moss-litter is excellent, and will grow grand vegetables; it is very strong. If you can get leaf-mould, spent Hops from a brewery, or very old rotten tan, any of these are the next best substitutes, and with a little lime and perhaps some of Thomson's Vine and Plant Manure will enable you to grow any kind of vegetables to perfection.—E. C. R.

4322—Diseased Tomato-plants.—The Bordeaux mixture and other things have been at various times recommended for destroying Tomato fungus, and doubtless these have done some good. A mixture of lime and sulphur would probably be as effectual, and these are, moreover, substantially free of salts. A pound of each boiled in 8 gallons of water would make enough wash for a large house. But

assuming, which I think I am justified in doing, that the Tomato disease under glass is due to bad management, especially as regard ventilation, altered conditions with the removal or shortening back of a few of the worse leaves will soon improve matters if the plants are not too far gone. In the latter case get fruits ripened as soon as possible, and pull them up. With perfect ventilation, and the roots properly cared for, there will be no disease.—E. H.

—What kind of disease have the plants got? What are the symptoms? For the most common of Tomato diseases the best treatment is to maintain a dry, airy atmosphere, in water sparingly, and cut off the worst leaves and burn them.—E. C. R.

4325.—Cabbages for market.—I am afraid your Cabbages when smothered with insects will not pay to send to market. Better give them to the pigs and plant the ground with Onions, Spinach, or some other crop.—E. H.

ORCHIDS.

PROMENEAES.

I AM in receipt of flowers of *P. xanthina* from "Jules Godefroy," asking its name, and if he can grow it in a cool-house in the South of London? In answer to this question I may say that usually there is one part of such a structure warmer than another, and if this part is slightly sunny I can assure him he may venture to try some of them. They are Brazilian plants, but they will thrive in a cool-house if a warm spot be selected for them. They are frequently pressed into the genus *Zygopetalum*; but with this arrangement I do not agree, for it appears to me that this latter genus is made a general receptacle for all those plants which are known little or nothing about. *Promenaea* was a genus founded by Lindley upon their being separated from *Maxillaria*, with which they were formerly included. They are showy, small-growing, seldom exceeding a few inches in height, and produce a goodly number of flowers, which last in perfection a long time. I used formerly to grow these plants upon a block of wood with a little Sphagnum Moss, but they required much attention to keep them supplied with water through the resting season, for they do not want drying up to such an extent as to shrivel them. If so treated they are difficult to restore to health and vigour again. Since the introduction of the small earthenware pans for the cultivation of Orchids, I have adopted them for *Promenaea*, potting them in a mixture of good brown peat-fibre or Polypodium fibre and chopped Sphagnum Moss, with good drainage. During the growing season they should have an abundant supply of water, both to their roots and overhead from the syringe, but during the winter just sufficient to keep them plump will be all that is necessary. They should be kept hung up close to the roof glass, and during their season of rest they must not be syringed.

P. XANTHINA.—This is the plant sent by "J. G." under the name of *Maxillaria citrina*, but which appears to be more correctly named *P. xanthina*, for the name *citrina* seems to have originated by mistake. It is a peculiarly bright and handsome species, and was discovered by Gardner nearly sixty years ago, who found it on the Organ Mountains, in Brazil, at some 5,000 feet altitude. It has oval, somewhat four-sided lobes, bearing a pair of short membranous leaves, flowers mostly in pairs, and these are thick and fleshy in texture, measuring about 2 inches across. They are bright citron-yellow, spotted more or less on the side lobes and front of the lip with bright-red.

P. MICROPTERA is a pretty little plant, introduced by Mr. B. S. Williams, of Holloway, and it was named by Reichenbach. I do not know much of it, but I think it is nearly related to the last named species. The sepals and petals are spreading, and of a soft creamy-white, and the lip has the lateral lobes very small, white, with some purple spots on the front lobe, and some transverse bars of crimson near the base.

P. STAVELLOIDES is at once the largest flowered kind known. It is of distinct colour, and the flowers, which are thick and fleshy, last a long time in perfection. It is rather more robust in its growth than those kinds previously named, but rarely exceeds 6 inches in height, and the sepals bear one or two flowers, which are about 2 inches across. The petals and sepals are light green, thickly spotted and spotted with transverse bars of purple, and

the lip has the side lobes of the same colour as the sepals, the intermediate being of a deep blackish-purple. This, although the handsomest of the kinds known, is not very often to be met with in collections; but it is one of the old plants that is well deserving attention from every amateur that cares for Orchids. I would urge my readers to cultivate an acquaintance with a number of these miniature gems. They are easily grown, and do not occupy much space. MATT. BRAMBLE.

CATTLEYA GIGAS.

THE enquiries of "M. J. R." about this plant are not surprising, more especially from what he tells me of the treatment it has received, and if you do not alter the system I fear that you will never bloom it. It will get small by degrees and ultimately die. This plant belongs to the labiate section of the family and comes from New Grenada. It was first introduced to this country in a living state by M. Linden, of Brussels, about twenty-three years ago, although it is reported to have been found the same number of years previously, and is said to be figured in the "Xenia Orchidaceae;" but the figure given appears as if it had been taken from a bad *C. Trianae*—in fact, to me it may represent anything. For this reason I adhere to the *Lindiana* name here given. Well, this *Cattleya gigas* is a grand flower, the form called *Sanderiana* especially giving the very largest blooms in the whole genus. It is said to grow mostly on the branches of trees, beside streams, or in the vicinity of water, and although the plants are found sometimes growing in the shade it is those that grow with a good exposure to the sun that produce flowers most freely. This is a condition which is recorded of this plant when growing naturally, and the best results come to those who treat it similarly under cultivation. The present year will be a curious one for this plant. It usually blooms about now, but I saw some grand varieties early in May. This species requires to be kept cool after flowering, so as to just nicely ripen its growth, but it should not be allowed to start during the winter, for these growths will not produce flowers. I have found it much the best plan to keep the plant dry for a time after its bulb is made, and at the same time it should have an abundance of light and air. As autumn comes it may be removed to a cooler position, and the moisture in the air will keep the leaves and bulbs in a plump condition, but if there is not moisture enough to do this a little water should be occasionally given. The cool temperature will prevent the eyes hurting, but some time towards the end of the month of February they should be removed to a warmer place, hung up close to the glass, and started growing with vigour. If "M. J. R." will keep his plants as stated above, he may not have flowers next year even, but he will get stronger growth, and from that again he will get bloom. He may rest assured that from growth that is made in winter he never will secure blossom. MATT. BRAMBLE.

A dwarf Bell-flower.—A very pretty *Campanula* is named *C. grandiflora Mariesi*, and it is dwarf in habit, making a large clump, enriched with deep purple-blue flowers of hold form. I have sometimes been asked by amateurs the reason of its too often unsatisfactory condition, and usually it is due to interfering with the roots. This *Campanula*, sometimes, but not often, called *Platycodon*, is one of those things that hates to be disturbed, and allowed to grow into a haxom mass, and under these conditions it is very handsome, as the flowers are remarkably large for the height of the plant. It will succeed in either the border or the rockery, and flowers freely at this season. I should like to see it more grown.—V. C.

Destroying wasps.—There is such a plague of wasps in many places this year that your readers will perhaps like to hear of a simple means of destroying them. Pour some turpentine down the hole leading to the nest and stop with a turf, or insert the neck of a bottle containing a small quantity—say a cupful. If this is done at night when all are at home the wasps will be found dead next morning. It is a simple but sure remedy if properly applied.—B. C. R.

FERNS.

A BORDER OF FERNS.

Too little use is made of the hardy Fern in gardens. A border of them is very charming, especially as seen in the accompanying illustration. The plants are associated with the graceful Bamboo. There are many spots in

cuttings may be hastened by taking out the earliest flowering spikes as soon as these are on the wane, and when the cuttings are 3 inches or 4 inches long, insert them in sandy loam, and place in a cold frame till rooted, giving the necessary attention to shading, watering, and ventilation. When rooted give them full exposure to thoroughly harden them for the coming winter, or if rooted sufficiently early

4334.—**Tulips and Forget-me-nots.**—As the spring season lengthens the Forget-me-nots naturally get leggy. Perhaps the position for the bed is too shady. If so, that will account for their legginess. There is quite a dwarf variety of the Forget-me-not, but we do not care for it. It loses in freedom and a certain gracefulness when so dwarf in stature. The Antirrhinum or Snapdragon is spoilt in a similar way. I am pleased you have asked about the Tulips, but they are rather dearer than the ordinary Dutch varieties. The best effect is got by planting them in distinct beds—that is to say, not to mix the kinds. One of the best types is Tulips macrospila, which was used very largely at Kew last year. It does not bloom until early May, but the majority of these fine Tulips flower late. This type has large carmine-rose flowers, very bright and pretty. It comes up evenly, and if you have a small bed, you may well plant it with this kind. T. elegans is rather earlier, and it is a noble Tulip. The flowers are intense crimson in colour, the segments setting narrow towards the apex, and pointed. It is remarkably rich, and a good bed of it makes a fine effect. The majority of these kinds have very robust leafage, broad, and of a glaucous colour. T. fulgens is perhaps the finest of the collection. The flowers are brilliant crimson in colour, and most effective; the tall scape rising from the broad, glaucous leafage is very handsome. T. spatulata (crimson-carmine) and the yellow-flowered T. retroflexa are of note, whilst you can also have a bed of the Parrot Tulips, which are very quaint and interesting, the segments gashed and out in a curious way, whilst the colouring is intensely rich and quixotic—crimson against yellow, and so forth. They are too heavy for the scape, and hang their heads in a characteristic manner; but this enhances their quaint beauty. Plant the bulbs in September or early October, putting them about 4 inches deep in well-drained, moderately light soil. It is a mistake to delay planting until the winter.—C. T.

4319.—**Box.**—This is one of the easiest and simplest of all things to grow. Take up the old Box-edging, shake out the soil from the roots,

OUR READERS' ILLUSTRATIONS: A border of Ferns with Bamboo. Engraved for GARDENING ILLUSTRATED from a photograph sent by Miss Robertson, Blairgowrie, N.B.

both large and small gardens when they can be grown to perfection, and it must be remembered that shade and moisture are essential, at least, in very hot and dry spots they will not thrive. We have often been struck with the beauty and usefulness of hardy Ferns in town gardens, where little else will thrive. If the soil be made moderately good at the commencement, and during the hot summer months water is given, the plants will make a grateful show, and prove a relief from the bricks by which they are surrounded. The autumn and winter seasons are at hand, when alterations may be carried out in the garden. A border of Ferns should be made, if possible, and the plants gain in beauty if grouped with the Bamboos, many of which are quite hardy and of delightful aspect.

OUTDOOR PLANTS.

HYBRID PENTSTEMONS.

The hybrid Pentstemons, which include all those varieties which have had their origin in Pentstemon gentianoides, are amongst the gayest of summer flowers. They are, as a rule, possessed of good habit and constitution, and always figure among the most striking plants in those gardens where justice is done to them. In favored localities many varieties are perfectly hardy in the open ground, and where such is found to be the case they should be allowed to remain, inasmuch as these flower much earlier and decidedly more freely than young plants. Sometimes it happens that the old plants are cut back by the severity of the winter, but if not damaged at the root the early days of spring will see them bristling with young shoots at the base, these making rapid headway when warmer weather arrives. On the other hand, in very severe winters, even with the protection of a cold-house or frame, the whole lot may be killed. Of this latter I had an experience in the winter of 1879-80, when I lost about 1,500 fine plants, all well rooted in the storn pots from the simple fact that no heat could be given them. The winter, however, was a severe one, some 25 degs. of frost being registered, and though exceptional, it serves to demonstrate that on the whole the stock plants or cutting pots must be out of the reach of frost to be considered safe. The best way of keeping up a supply of these plants is to secure plenty of stout cuttings in the autumn, or as soon after flowering as the plants will produce suitable material. The formation of good

they may be potted off singly and allowed to pass the winter in pits or frames from which frost is excluded. Such plants as these by the time they are required in spring should have three or four strong breaks and be very vigorous, and in time will make a much more superior display in the flower garden than those whose propagation is deferred till spring, and when they have to be pushed along in heat to secure even presentable plants. It is well worthy of consideration that plants required for propagating purposes should not be planted in the flower garden proper, but in some secondary position where they may be operated on at the right moment. In large gardens there are plenty of such places, the foot of a Rhododendron bank, or the front of a shrubbery border, and so forth, and in these positions when stock is secured, the old plants may be allowed to take their chance, when with the assistance of a handful of short litter about them at the base many will probably survive the test, and, providing early flowers in consequence, well reward the experiment. J.

ERIGERON MACRANTHUS.

This is a fine plant of spreading and tufted habit, and all through the season it is studded with a mass of flowers almost exactly like those of the common Daisy, pink when they first open, afterwards fading to white. It is very effective as a broad band around, or edging to, a mass of some bright colour, especially in a bed upon the Grass. It is quite hardy, and may be propagated by division, but it succeeds very differently under this method of increase. The best way is to raise it from seed, which it produces and ripens freely. There is hardly any need to gather seed and sow it, as late in summer seedlings spring up in myriads around the flowering plants. As many as are required can be taken up, and pricked into a suitable bed of fine soil. If in a cold frame for the winter they will make good plants for putting out the next season, hardy in the sense that unless the weather is very severe the plant is unharmed, but it is best to divide the plant into about two-thirds of the same, then divide it into little pieces. If you wish to plant again directly choose the youngest and shortest pieces, cut off the roots slightly, and replant sufficiently deep to allow of 2 inches to 3 inches

OUR READERS' ILLUSTRATIONS: Erigeron macranthus. Engraved for GARDENING ILLUSTRATED from a photograph sent by Miss Wolley Dod, Edge Hall, Malpas.

of the Box to appear above ground. The remainder may be placed in some rich and light soil, and will come out well the following season. If Box has been growing for some time in one place it is necessary to add a little manure at the time of replanting, as it is a very hungry shrub. —P. U.

— This does not grow freely in all classes of soil, a rather light loam suiting it best. In heavy damp clay soils, Box is not suitable for an edging. There are several distinct varieties, but the best for edging is a dwarf kind well known in gardens; unfortunately, this is sometimes mixed with a taller growing sort, which makes a worse edging than if the taller sort was used by itself. Box-edgings must occasionally be taken up and relaid. One yard of a good edging parted out will make three yards when relaid. The ground under the edging must be well dug up, and be trodden and beaten down quite firmly; rake the surface quite level; strain a line tightly where the Box has to be laid, beat down again with the back of a spade. This will leave the mark of the line distinctly upon the surface, and the line may be removed, as it is easier to cut the mark in the soil. Lay the Box in deeply and make very firm. —J. D. E.

4284.—**Carnations, &c.**—Carnations may be distinguished from Pinks by their habit of growth, the grass being of a bolder character, of taller growth, and much less dense; they also begin to bloom just as the Pinks are over and continue right into the winter; Picotees are distinguished by having the outer borders of the petals distinctly edged with colour, pink, rose, crimson, scarlet, vermilion or purple on a white, yellow, or buff ground. Carnations are either selfs (that is of one uniform shade) or flaked and striped with other colours; when boldly marked with longitudinal streaks and splashes they are properly called bizarres; they may have more than two colours in the petals; the yellow ground varieties sometimes being varied with a white central band down each petal in addition to the crimson or purplish flaking. —A. G. BUTLER.

— Carnations and Picotees are arranged in classes after the following manner: Selfs, all of one colour; flakes, petals flaked with rose, scarlet, crimson, or purple, and are all named after each colour—scarlet flakes, rose flakes, &c. Bizarres have two or more colours and are named after the predominating colour—scarlet bizarres, purple bizarres, &c. In Picotees the colour runs round the edges of the petals, only the other parts being clear, and are called red-edged, purple-edged, &c., according to the colour of the edging. What are termed laced Pinks have an edging, sometimes heavy and sometimes lightly laid on, of purple, rose, red, &c. The Border Pinks (white, red, &c.) are chiefly selfs. —E. H.

4324.—**Plants for a sloping garden.**—One would like to know a little more of the situation and its surroundings. In some positions Hollyhocks will be charming, in others they would not suit at all. Again, the White Japanese Anemone, Polygonum cuspidatum are very striking plants for filling in a hollow in the lawn, when hacked up with shrubs. Hardy Fuchsias, Roses, and Carnations are always effective in suitable positions, and leave nothing to be desired, or we may fall back upon tender things, such as a mixture of foliage plants, or flowering and foliage plants combined. Any of these in the hands of a person of taste will make a respectable group. The cheapest arrangement will, of course, be the hardy plants, and there is an endless variety to select from to suit every season of the year. Herbaceous and Tree Paeonies, Tritomas, Herbaceous Phloxes, Delphiniums are all splendid things in their way. —E. H.

— It is probable from the description that your garden is shady. If so, you must confine your selection of plants to such things that will live only in shady places. If the position is such as described, plant the Solomon's Seal, Lily of the Valley, Spanish Squills, and Ferns, which will thrive under such conditions. If not shady, you may plant a variety of things. See reply in GARDENING, July 22, 1893, "A house border," a selection of things is given there which will suit your requirements. —C. T.

— Only very hardy plants will thrive in such a position as you describe. Amongst flowering subjects the Herbaceous Spiraeas will admirably, especially such kinds as *A. latifolia*,

filipendula, and palmata. The Japan Anemones will also succeed very well. The Rocky Mountain Columbinas are so hardy that they thrive in sun or shade, if they get plenty of root moisture. The Mimmals would do well in such a position. —J. C. C.

— It would appear that this garden was a good deal shaded. I should therefore recommend you to plant it with Ferns, Solomon's Seal, Lilies of the Valley, Snapdragons, Columbinas, Perennial Phlox, Pansies, and Violas. —A. G. BUTLER.

4336.—**Lilies of the Valley.**—It is evident that the crowns are much too crowded together. Probably they have been in the same position several years, and under such circumstances get thoroughly out of condition. It is a mistake to suppose they will go on for ever without some assistance. Probably it is a long time since they received a top-dressing of well-decayed manure. I should advise you to lift them, select the finest crowns for planting in the border, the others being planted elsewhere. Give the soil a good dressing of well-decayed manure, and put the crowns from 9 inches to 1 foot apart. Give water occasionally if the weather is dry. —C. T.

— The crowns of your Lilies being so crowded is the reason why they do not flower. The richness of the soil causes such a vigorous growth that they do not ripen sufficiently to mature flower-buds. You must discontinue using the manure for a year or two. A better plan still will be to thin out the plants at once over half of the space, cutting them out with a strong knife just under the surface. This will let in light and air and harden up the crowns that are left, which will probably bloom next year. The remaining half of the bed should be taken up and transplanted next February. Select the strongest crowns for planting, and give them more room, but do not use any manure. —J. C. C.

— The plants are probably too much crowded, for to such a position and in the soil you mention they usually flower abundantly. I should recommend you to take them up, select the best crowns, and replant them about 8 inches apart, after which I should add a top dressing of well-decayed stable-manure. —A. G. BUTLER.

4327.—**Treatment of Jessamine.**—The plant has evidently made too much growth, and all the vigorous flowering shoots are formed at the top, whereby the flowers are produced there, and none at the bottom. The only remedy would be to cut a number of the old stems down to near their base, leaving sufficient, when nailed in, to cover the wall very thinly. Where the old stems have been cut, young shoots will be produced, which should be nailed in, near the base of the tree, and these will in due course produce flowers, so that the tree may be furnished with bloom, from near the base to the top of the wall. The best time to cut them back is in the early spring, before they start into growth. —J. D. E.

— If your plant is bare at the bottom part you may cut it back in the spring. If not too high, I would bend over the strongest shoots; this will cause them to break into bloom from laterals. —P. U.

— When the growth is much crowded Jessamines do not flower very well. They bloom on the young wood, and it must be thin enough to get ripened. The proper time to prune Jessamines, if flowers are wanted, is in spring; if well thinned out then the new growth will flower freely. It may be necessary to cut out some of the old wood in order to let in air and sunshine to harden the young shoots sufficiently to enable them to form flower-buds. —E. H.

4326.—**Pansy seedlings.**—Plant them out at once. It is not an ideal position for Pansies, but they would succeed well under such conditions. If you put them out at once, they will develop into excellent plants before winter. This is important, and if permitted to remain in a cold frame throughout the winter they do not succeed satisfactorily. Pansies are not the things to coddle in any way. The best soil for them is one that is moderately light, cool, fairly moist, and deep. If allowed a certain amount of shade they will succeed still better, as it is dryness and a hot, scorching sun that promote all kinds of disorders. Plant carefully, and throughout the remainder of the summer and in early autumn water them freely if the weather is dull and dry. They should make good plants for next season. —C. T.

— An east border will do very well for Pansy seedlings. Plant from now to October for spring bloom. —E. H.

— The position would answer fairly well, and, if planted out at once, the seedlings would get well established before the winter and be stronger than if coddled in a frame all next spring. —A. G. BUTLER.

INDOOR PLANTS.

4278.—**Begonias in pots.**—A very important point is to get the tubers thoroughly matured or ripened before the winter sets in. To this end the plants should be turned out-of-doors as soon as the flowers are past their best, choosing a moderately-sheltered and sunny spot. Gradually reduce the supply of water until by the time the leaves turn yellow and fall the soil is quite dry; hose them about the end of September, or before there is more frost than just enough to touch the tops. I believe the best plan is to shake the tubers out of the soil, and keep them in half dry Cocoa-nut-fibre; this should be done as soon as the stems have quite fallen away. Keep them where no frost can penetrate, but not in a very warm place—40 degs. to 45 degs. is the best temperature—and take care that they do not become either at all wet or dry enough to become limp or shrivel, and they will be all right. —B. C. R.

4308.—**Forcing-beds in a stove.**—Neither tank nor water is necessary. Simply enclose a sufficient length of the three pipes (one would scarcely be enough, though two might do) with brickwork, fix some wooden or iron bearers across, 18 inches apart, and lay thereon one or more sheets of the galvanized corrugated iron. Upon this place 3 inches or 4 inches of fresh Cocos-nut-fibre, which keep moist, and if necessary cover the whole in (over the outtings, &c.) with a light sash or two, or come loose sheets of glass, laid on a light framework of wood. This will answer your purpose quite so well as the most costly tanks, &c. —B. C. R.

4332.—**Passion-flower.**—The woolly insect is a species of coccus, and allied to the "American blight." If you paint it thoroughly with sweet-oil the insects in the woolly covering will be killed. Layering would be more certain than taking cuttings, but, as a rule, Passion-flowers throw up numerous shoots from their roots which can be taken up with root attached and separately planted. Such shoots invariably grow into vigorous plants, but it will be two or three years before they can be expected to bloom. —A. G. BUTLER.

— Your plant has evidently got a very bad insect pest called mealy-bug. It is extremely difficult to eradicate, especially from large and strong-growing climbers in a conservatory. Apply any of the numerous insecticides advertised in these pages, and use it freely. Cold water syringed on it with considerable force will also kill a great number, but I fear you will never quite eradicate it from a strong Passion-flower. Cuttings of young growth about 4 inches long will strike readily in a gentle heat if kept close for a few weeks. Choose side growths as much as possible, and use plenty of sharp sand in the compost. —P. U.

— The woolly sort of insect is most likely the mealy-bug, and it is not very easily got rid of. The best thing to do would be to cut the plant well down, so that the part remaining may easily be washed with soft-soapy water. Even when the stems are well washed the insects will appear again the following season; but if they are watched and destroyed as they show themselves they may thus be got rid of. Cuttings put in early in the autumn will form roots, but all such hard-wooded plants ought to be placed in handlights or under bell-glasses to form roots. —J. D. E.

4323.—**Musas from seed.**—I have never raised Musas from seed, and cannot say whether good seeds are difficult or the reverse to obtain. But there is not the slightest difficulty in obtaining plenty of plants from offsets or suckers. When I grew Musa Cavendishii somewhat largely plenty of suckers always grew away from the base of the fruiting plants, and these taken off with roots would make fruiting plants in from eighteen months to two years, sometimes less—but I am speaking now of small offsets only. —E. H.

4299.—**Double and Single Begonias.**—A great deal depends upon the varieties, the old-fashioned kinds making a far more free and rapid growth than the new dwarf-habited varieties, with erect flowers and thick, broad foliage; but if the plants were raised, as it appears from the photograph, inserted in March,

they have made a remarkably free and robust growth, and must have had the best of treatment throughout. Such specimens are seldom seen even in London or anywhere else, and when grown from three-year-old tubers instead of cuttings, if in good-sized pots—10 inches or 12 inches—they should continue to bloom until the middle or end of September at least, especially if the vigor is kept up by the use of weak liquid-manure, soft-water, &c., given once or twice weekly.—B. C. R.

FRAGRANT STOVE PLANTS.

BEAUMONTIA GRANDIFLORA is figured here with. This is a famous genus of Dogbanes, but now neither this nor any of the genus is often seen—in fact, there seems to be quite a lack of interest in many of the famous old stove plants. *Beaumontia grandiflora* was introduced many years ago, and the last time I remember to have seen it in flower was at Syon House, Isinworth, the seat of the Duke of Northumberland, about forty years since. At that time splendid old plants were to be seen blooming in this collection. Its trumpet-shaped blooms are large, and pure-white. It succeeds best when planted out in a well-drained border, and is more likely to flower when so treated. It should have an intermediate stove to grow in, one in which the temperature does not fall below 50 degs. during the winter will suit it admirably. The soil should be good turfy loam chopped up roughly with the spade, a little peat or leaf-mould with some sharp sand added. The *Beaumontia* may be grown in pots in this soil until it gets large enough to plant out in the border. Amongst the most fragrant of stove flowers are the following—

THE *JASMINES* are especially noteworthy in this respect, and one of the more pronounced is *J. Sambac* fl.-pl., which comes from the East Indies; its exquisitely scented flowers are ivory-white in colour and double. They are borne on short, lateral shoots, usually furnished with a few small leaves, that proceed from the axil of the leaves on the stronger growths, which in a healthy plant generally keep on blooming all through the summer and autumn so long as its growth is being made; this is an advantage, as it admits of almost every bit of bloom it makes being utilised. Cuttings strike easily when they can be obtained with some freedom of growth in them, but the shoots that are disposed to form flowers as soon as they have attained 1 inch or 2 inches in length, even if they make roots, are a long time before they can be induced to grow freely. In the spring, about the beginning of April, cuttings of the right description may generally be had; these should be a few inches in length, but not with the wood too hard or matured; take them off with a heel and put them singly into small pots three parts filled with a mixture of three-fourths sand to one of loam, the surface all sand; keep moist, close, and shaded in a temperature of 70 degs., or a little more. They will strike in a few weeks, when use them to bear the full air of the house and stand them on a shelf or some other moderately light place. When a fair quantity of roots is made move the plants into 3-inch or 4-inch pots, using good turfy loam with some sand; they will now do best with a brisk stove heat, giving air in the day-time with a little shade when the sun is powerful, syringing daily, maintaining a moderately moist atmosphere. After a few inches of growth have been made, pinch out the points of the shoots, for the plant has naturally a thin, erect habit of growth, and to induce the formation of soft-leafed branches it is necessary to resort to stopping, although it is by no means desirable to attempt to restrict it to a bush-like form. It is best grown round a pillar, or wound round a few tall sticks inserted just within the pot; being a spare rooter, it must not have too much root room, either in a pot or planted out. In July move them into pots 3 inches or 4 inches larger, and again stop the shoots. Treat generally through the summer as recommended until the middle of September, when cease shading, give more air, less moisture in the atmosphere and reduce the temperature; during the winter 60 degs. or 65 degs. in the night will be enough, only just keeping the soil a little moist. Towards the end of February increase the warmth, and when growth has fairly begun again pinch out the points of the shoots, and move to pots 2 inches

or 3 inches larger. In the matter of heat, moisture, air, and shade treat as in the preceding chapter; they will this season bloom from all the growths they make. When planted out, the soil to which their roots have access must be limited to a small space, or it will meet likely get sour. If confined to pots, all they need in subsequent years is to give more room as it is wanted, not attempting to shake out the plants or disturb the roots more than can be avoided. A little manure-water in a weak state will be an assistance. The plants will last for many years. There is a single-flowered form of this *Jasmine* differing little in its appearance except in the flowers. It succeeds under similar treatment to the kind under notice. This *Jasmine* is liable to the attacks of most insects that affect plants grown in heat. Thrips and red-spider, which are partial to the leaves, can be kept down by syringing. If any insects of a worse description, such as scale or mealy-bug, make their appearance, sponge with insecticide, finishing with clean water.

THE *STEPHANOTIS* is another favourite. It is as much grown as almost any flower for its delicious fragrance. It will grow in either peat

Beaumontia grandiflora.

or loam, and strike freely from cuttings made of the preceding season's shoots, and portions that have not got too hard should be used. If cuttings consisting of a couple of joints of these are, during the winter, put in thickly in 5-inch or 6-inch pots and stood in a temperature of 60 degs., they will callus over in a few weeks, when they may have 10 degs. more warmth, which will enable them to root freely, or young shoots such as break from the old stems in spring may be taken off, when 8 inches or 9 inches long, with a heel of the old wood. These, if kept a little close and in a temperature similar to that recommended for cuttings of the mature wood, will root directly. When well rooted put them singly in 4-inch pots in good fibrous loam, with sand added proportionate to the nature of the soil. They will grow away if kept in a temperature of 60 degs. or 65 degs. in the night, with a rise by day. *Stephanotis floribunda* is of twining habit, and as soon as the plants begin to grow each will require a stick as support. When the shoots have reached a couple of feet in height remove two or three of the top joints to cause the production of two or more growths. The plant comes from Madagascar, and can stand a good amount of heat; consequently, through the summer months it will bear a temperature of 85 degs. to 70 degs. by night, with from 70 degs. to 80 degs. in the day. It does best with a liberal admission of air in the day-time, so as to permit of the air of the house getting drier than if less is given. It requires no shade further than is found necessary to keep the leaves from scorching. If by the beginning of July

the pots are found full of roots, move into others a couple of inches larger. Syringe the plants in the afternoon during the growing season until September, when give more air and reduce the root moisture as well. From 55 degs. to 60 degs. night temperature will answer through the winter, with just as much moisture in the soil as will keep the leaves from shrivelling. About the beginning of March raise the temperature, and increase it still further as the sun gets warmer. Give more water to the roots, and as soon as growth has commenced move into pots 4 inches or 5 inches larger, using loam, which should be of a good turfy character, and such as will not soon decompose. Ram the soil quite firm, and fix trellises on the pots whereon to train the shoots, or run them up wires or strings over the roof. Before the shoots begin to grow stop the plants or cause them to break. When the blooming is over the shoots may be shortened back, and pots from 4 inches to 6 inches larger should be given. The pots to which the plants were last season moved will be large enough for the next two years; manure-water should be given at the time of active growth. Cut the shoots back so far as necessary after blooming, as advised the preceding season, and treat as before. The plants will last for many years if a few inches of the surface soil is removed and replaced with new. I have spoken of their being grown on trellises in specimen fashion, but they do better close under the roof near to the glass, and even if they are wanted to bloom on the trellises the shoots should be trained near the glass during the growing season, and then wound round the trellis when fully matured. But the plant is never seen to so much advantage as where permanently trained under the roof, and if, in addition, it can be planted out in a bed of well-prepared soil 4 feet or 5 feet square it will keep on growing and flowering for many years. Where there is plenty of room for the head to run a plant will continue blooming for months. Scale and mealy-bug are very partial to it. Should these affect it, a thorough dressing with insecticide ought to be given when the plants are in a dormant state during the winter, and the dressing repeated, so as to make sure of destroying both the mature insects and also their eggs.

AMAZON LILY (*EUCHARIS AMAZONICA*) is a very fragrant flower, and—in large gardens only, of course—a span-roofed house is often devoted to them. I think that the old drying system is a great mistake in the culture of this plant, and responsible for much of the "Eucharis mite" that we hear about. My plants, which are very large, and in 18-inch pots, are placed in a house of which the temperature is 80 degs. They are optionally syringed with clean, soft water, and shaded from hot sun. Potting is only done once in five or six years, and the soil used is sound loam, with sufficient broken charcoal and sand to render it porous. This, together with an occasional watering with manure-water when making growth after flowering, seems to meet their requirements exactly. Get good, healthy plants to commence with.

THE *GARDENIA* is very popular, but not so much as formerly. The plants must have a brisk, moist temperature. During the growing season place them in the clearest part of the stove, and well supply them with liquid-manure. When the growth is complete, and the flower-buds forming, expose them to full air, and for months I keep them in a cool-house with *Camellias*. When bloom is required they are again returned to the warm corner of the stove. The only drawback is that insect pests of every kind attack them. Mealy-bug, white and brown-scale, thrips, and red-spider each assail them. The best remedy for these pests is to lay the plants upon their sides, and then syringe them, when in a dormant state, with water heated to 120 degs. Then follow with a dressing of some approved insecticide. *G. radicans* is a popular kind. It is dwarf, free-blooming, not very difficult to grow, and very fragrant; hence its name of Cape *Jasmine*. There are many other fragrant stove flowers, but the chief kinds have been mentioned. *Hedychium* are very sweetly scented; also the *Crinum*s, but they are not so freely grown as the former. W.

4328. —Cutting back Oleanders.—Oleanders have a tendency to make lanky growth, and in a few years become very unsightly. There are two ways to keep them in

order—either to cut down the old plants or plant young ones. They may be propagated from cuttings put in sandy soil about the end of summer, and kept under bell-glasses or band-lights until they have formed roots. If the plants flower early they should be cut down at once, and as soon as they start into growth repeat them if this be necessary, and if they make good growth by the end of the season they may be expected to flower very well next year. If cut down now there would scarcely be time for them to make good flowering growths for next year in a cold greenhouse. However, it would be better to cut the plant down at once, as there is yet time to make some growth.—J. D. E.

— Nerium Oleander may be cut back at any time, but it is almost always done to a certain extent of loss. I would wait until the flower-buds are well formed, then cut out the shoots containing these, and strike them in a hot greenhouse or stove. After this you could cut back your plant as much as you liked, and it would be sure to break well. The hlooms upon the outtings would in the meantime open and give you a nice display.—E. U.

— If cut back now they will not flower next year if all the shoots are cut; but if the plant is a large one the longest shoots may be taken, and probably those left unshortened will. Plants must be cut back early in spring, and be started in heat to flower the next year.—E. H.

4303.—Pelargonium "Master Christine."—I have grown Christine, and after it Master Christine. Both are almost identical in leaf and bloom. Bright yellow-green would be a tolerably good description—certainly no trace of a zone in either kind. The flowers are bright-pink, and produced very freely. The plant is a first-rate bedder, good in habit, rather dwarf, especially Master Christine, and impatient of moisture. Must be kept rather dry. Too apt to run to seed, but seedlings from them follow very much the parent plant—at least, I repeatedly found them do so.—FLORIST.

4277.—Winter flowers.—Try the following: Chinese Primules (single and double), P. ohonica, Cinerarias, Persian Cyclamens, Camellias, Roses, Zonal Pelargoniums (Geraniums), Abutilons, Bouvardias, Cape Heaths (Erica byemalis and others), Epacris in variety, Correas, Chrysanthemums (late flowering vars), Salvias, Heliotropes, Marguerites (Paris Daisy), Roman and other Hyacinths, Tulips, Narcissus of sorts, Tree Carnations, and, in the coolest positions, Christmas Roses and Violets.—B. C. R.

— The following are useful winter flowers: Primulas, double and single, including P. ohonica, Cyclamens, Cinerarias, Chrysanthemums, Begonia insignis, Arm Lilies, Zonal Cereoniums, Coronilla glauca, and its variegated variety. Ivy-leaved Geranium Mademoiselle, Bouvardia, Geniste fragrans, Erica gracilis autumnalis, E. byemalis, E. Wilmoreana, Abutilons in variety, Tree Carnations, and bulbs in variety, including Freesias, Roman and other Hyacinths, Tulips, &c.—E. H.

4339.—Carnations in pots.—The old plants of Carnations now in 6-inch or 32 sized pots may be kept in these until the spring, and be planted in 8-inch in March. They may be wintered either in the cold frame or the unheated greenhouse, and it is possible they may do much better than those which have been taken from the parent plants and have been re-potted. The young plants should be potted in small 60's when they are taken from the parent plants, or they may be planted out where they are to flower in the open garden. If rooted layers can be taken off and be planted out so early as August they will have ample time to become established before the winter.—J. D. E.

Hyacinths in Moss.—I much wonder that no one has recommended growing Hyacinths in Moss. I grow a number every year thus, and they produce very fine hlooms. One, two, or three bulbs in an old china bowl, cascade-pot, or even empty jam-jar, make a lovely show. The Moss must be packed very tightly at the bottom, and kept damp after the roots have started. I give doses of weak liquid-manure occasionally, and the superabundant moisture must be poured off at times.—L. T. F.

Drawings for "Gardening."—Readers will kindly remember that we are glad to get specimens of beautiful or rare flowers and good fruits and vegetables for drawing. The drawings so made will be engraved in the best manner, and will appear in the course of the Gardening Illustrated.

FRUIT.

VARIETIES OF GOOSEBERRIES.

WHEN there are hundreds of varieties of Gooseberries to select from, and probably the grower in many instances does not want more than half a dozen, he is at a loss when he scans the list to know what is best, and often gets sorted out at all untable. With so many to select from, the grower should get both early and late kinds. To get a long succession planting in different positions is necessary, and if a north wall can be spared for a few cordon trees, there is no surer crop than the late Gooseberries. This season the trees suffered badly from spring frosts, but these on a wall escaped, being later and protected from the cold winds. On a north wall as cordons the fruits can be had much later, and the trees get the cool treatment they so much like; they are also so easily protected from birds that I often wonder that more trees are not grown in this way, as often a bare north wall may be planted with a few trees to furnish the bottom of a wall with taller fruit trees at the top. Gooseberries do well as cordons trained to iron rods or stout Larch poles; they require so little attention grown in this way, occupying little room, and are ornamental in a fruiting state. Gooseberries well looked after are a paying crop, as they may be used in a green state, and when ripe with protection from birds hang a long time. When grown as cordons on walls they are more readily protected from caterpillars than in a bush state, and if a few loads of manure are placed over the roots as a mulch in the early part of the year or in December, raking away the old material, caterpillars are rarely troublesome, and the removal of the old loose soil removes any insect larvae that may exist and the trees get the feeding required. These trees often suffer from want of feeding, as in many gardens there is no thought as to providing bushes with manure, but when given annually the size and quality of the crop are superior. I have seen very old hedges that had been on the same ground for many years lifted and replanted, and with the roots in a good condition the trees have given wonderful crops. Of course I do not advise planting old trees, as young ones with good culture soon give a heavy crop of fruit, but I would recommend more feeding in poor soils after the trees get into a bearing state. Those who require Gooseberries for preserving cannot do better than grow Red Warrington and Ironmonger. The former is a fine Gooseberry for a north wall, and if kept spurred in closely does well. In the white class, Whitesmith, King of Trumps, and Aline are good, whilst Industry, Conquering Hero, Forester, and Rough Red are good reliable kinds in the reds; Leader, Early Sulphur, Yellow Champagne, and Tiger are good yellows; Green Coccyne, Green Overall, Surprise, and Telegraph in the green varieties. In the matter of flavour many of the small fruits, such as Pitmaster Green Gage, Red Champagne, Early Green, Heiry Early Red, Heiry Bright Venus, and Early Sulphur are beautiful fruits for flavour. In this small selection I have only given a few varieties, but sufficient for most purposes, unless required for exhibition. For the latter purpose size is essential; for early gathering in a green state a large early Gooseberry is best. When a wall or fence is devoted to this fruit there is no difficulty in preserving the huds in the spring by netting over the bushes. H.

Apple from cuttings.—I venture to send for your inspection a few specimens of Apples grown from cuttings that had been sown off and simply stuck into the ground. Of course, they are not yet fully developed, but even now (to me at least) they are very interesting. No. 1 is sent in of a local kind called "Tulloch Ans," or "Laesies." Twelve outtings were put in over four years ago, and ten out of the twelve have borne fruit every year, although only about 4 feet high. One of these has now thirty-six good fruits. No. 2 is called here "Bitter Swouts." The outtings were put in at the same time as those of the other, and have fruited every year, bearing now a fine crop. Both of these are free bearers. Of Annie Bligh's outtings were put in, only two surviving to bear

fruit. The Apples are larger than on the old tree, yet they are few in number.—W. TREATON, Rosera.

4320.—Manure for fruit-trees.—There are special manures suitable for fruit-trees, and perhaps one of the simplest and best is bone-meal. This used in conjunction with stable-manure will answer every purpose for all kinds of fruit. The bone-meal should be forked into the border, and the stable-manure used on the surface as a mulch. Most of the chemical manures are, I think, too expensive. Possibly if the demand was larger the price would be lower, and in time these things may right themselves.—E. H.

— Farmer's manure is as good as anything for fruit-trees. Powdered or crushed bones are excellent, especially for stone fruits. It is perhaps best to apply the manure to the surface, as this encourages the roots to the top. I do not care to use artificial manures for fruit-trees, as they have a tendency to encourage the development of too much and too vigorous young wood.—J. D. E.

4333.—Pears.—It is unfortunate that you want Pears for a badly-drained clay soil, as the fruit is liable to crack, especially in a dry season. The Jargonelle is as likely to succeed on the wall as any other. Citron des Carmes is a Pear that ripens in August. The tree makes a good standard, but under all conditions the fruit generally cracks just as it is on the point of ripening. Williams' Bon Obretien does well as a standard, and ripens in September. Louise Bonne of Jersey follows in October, and the tree makes a good standard.—J. C. C.

— The following are good, hardy, free-bearing sorts: Bazel, Angouleme (plant on mound and keep the roots out of the clay), Mme. Treve, Windsor, and Williams' Bon Obretien.—E. H.

4269.—An old Apple-tree.—It is rather difficult to say what is the best thing to be done with an old Apple-tree that does not bear well. The tree may be in an impoverished soil, and if so, might perhaps respond to generous treatment in the shape of manure, liquid or otherwise. Or if making too much wood, backing the roots might restore it to fruitfulness, or if the tree is worn out, the best course will be to grub it up, refresh the site with manure and some good soil, and plant a young tree.—E. H.

4280.—Fig-trees under glass.—Unless the roots of Fig-trees are confined, they frequently make a lot of wood, which in a cool-house does not ripen well. If the roots can be got at and lifted and a lot of brick-rubble, mixed with old plaster, rammed in, they will do better. Keep the growth thin by removing weak shoots. If the house is heated the growth should be regularly pinched when half-a-dozen leaves have been made. If the roots are under control liquid-manure may be given freely when the fruits begin their second swelling, and rich mulchings are beneficial in keeping the roots near the surface. Figs should be trained in a light position. They are sometimes planted under Vines, but they do not under such circumstances get justice.—E. H.

BEGONIAS PLANTED OUT.

By my experience these favourites and most charming plants succeed much better in the open ground than under glass, and with a tithe of the care and attention required by pot-plants. Of course, where the atmosphere is at all smoky, the choicer kinds must be kept indoors, where the flowers will come so much finer and cleaner than outside; but with the advantage of a pure air, and especially if this is naturally somewhat moist, they certainly grow faster and stronger, and develop a dwarf, sturdy habit, with a thickness of leaf and petal that is very seldom found among plants grown under glass. They are not at all particular as to soil, and though a moderately light steeple of a preferably loamy character is perhaps more suitable, I find them thrive remarkably in the stiff and cold clayey loam that prevails about here. Whatever the soil, it should be well worked and made tolerably rich by the addition of old hot-bed manure, decayed spent Hops, leaf-mould, or the like, and a most important point is to keep the soil regularly moist—at least, until the young plants are thoroughly established and strong. If the seedlings are allowed to become really dry twice or thrice only they step growing altogether, and in some cases never do any good subsequently. A bed of quite small plants here, from tiny tubers of last year, planted out the end of June, are now nearly of a good size, and just expanding their first blossoms. E. C. R.

HOUSE & WINDOW GARDENING.

PALMS AND CYCADS FOR ROOMS.

PALMS and such a Cycad as *C. revoluta* (here figured) are excellent plants for rooms when a proper selection is made. Several of the Palms are practically hardy—at least, they will live in a temperature of from 40 degs. to 50 degs. The Cycad looks well under these conditions, and is a change from the various things used in windows. The great point always is not to give water too freely, or allow it to stand in the saucers. When watering give plenty at one time, not dribble, whilst the syringes should be brought into requisition to remove dust and dirt from the foliage. A good loamy soil, with a few crocks in each pot, suits this class. *Chamaerops Fortunei* amongst Palms is well worth a note. If the house is large, it is a fine Palm for standing about in halls, where it has a fine aspect by reason of the bold, striking character of the foliage. *Phoenix dactylifera* and *P. reclinata* are very useful, also *Areca luteocens*, which is a remarkably handsome Palm, the foliage delicate-green, and the stems quite of a yellow colour. Then one may include also *Areca sapida*, *A. Baueri*, *Latania borbonica*, and the *Kentias*. Several of them are very large growing Palms,

compost of two parts turfy loam to one of leaf-mould, with a little soot and sand. The corm should be placed an inch or two below the surface (leaving room for a rich top-dressing in June), and the pots can stand in a hack yard, on a thick bed of ashes, or on the leads, if necessary, though preferably in a garden frame. Here they will soon throw up their sturdy spikes of foliage, to be followed during the summer with tall sprays of blossom of every lovely shade, from palest lemon to deepest maroon, through rose-pink, carmine, scarlet, crimson, and terra-cotta. In fact, the exquisite hues of Gladioli are endless in variety; many of the flowers being blotched and spotted with deeper colour too. Nothing can be more decorative for a drawing-room, especially when well grouped with foliage plants and Ferns, and the plants can be lifted in as soon as the first bloom is open, after which they will not fail to produce all their blossoms without much sunshine. Amongst the Nancieans group some of the finest are as follows: Harry Veitch (pale-yellow and maroon, with crimson spots), President Carnot (with enormous carmine petals, spots blotched with pale-apricot and deep-crimson), A. de la Devanays (salmon-coloured, with orange spots), Maurios Vilmorin (mauve, with purple and yellow blotches), P. Duchartre

had, for this too bears slight forcing, by which its time of blooming is put forward to April, while in the open air it blossoms in June and July (according to the aspect and position of the border), thus covering the time until the open-air "Harrisii" Lilies and the speciosum group are open in July and August. Tiger Lilies (*L. tigrinum*), *L. auratum*, and *L. neilgherrense* can be had up to the end of November (the bulbs for late work being grown entirely in the shade of a north wall, when specially grown pots of the

USEFUL HARRISII LILY are the only representatives of the family until spring comes again. Most Lilies are, however, best grown without heat, a cold frame, with 6 inches of ashes at the bottom, being the most suitable place in which to cultivate them, although it is possible to do without even this slight protection, by covering the pots deeply with ashes in winter, in a back yard, or in boxes of ashes on the leads. Lilies do well in cities, even in the smoke of London, and are therefore especially worth a trial by town-dwellers. Their special needs in cultivation are as follows: First, that the bulbs should be potted immediately on arrival in this country, for which reason they should be ordered beforehand, when the horticulturist will forward them as they arrive. (N.B.—The first consignments of Lily-bulbs are usually not properly ripened, therefore, those which arrive a month later are to be preferred). A 6-inch or 7-inch pot is usually large enough for a single bulb, and these must be well-drained (the crocks being covered with Moss, dipped in soot), and half-filled with a compost consisting of two-parts turfy loam to one of leaf-mould, with a little very old hot-bed stuff, soot, and sand. This compost can be procured from a horticulturist if necessary, and should be used in a half-dry state, the bulbs being heat without water through the winter. Having placed the bulb on the soil, low down in the pot, fill it up with the same until within 2 inches of the top, leaving this space for top-dressing with rich soil in the spring. The potted bulbs must now be placed in a cold frame or box of ashes and covered to the depth of 2 inches with fine dry ashes, when they will need nothing more until the spring, when they should be relieved of their covering, and watered when thoroughly dry. Air they must have as much as possible, and as the stems grow the top-dressing of old manure and a little soot may be applied to induce fine surface-roots, on which their beauty largely depends. Green-fly must be kept at bay by sponging or syringing, for it is very apt to attack Lilies in their earlier stages, and the pots should be shaded from great heat in the summer and watered regularly. One after the other the plants will open their buds, when they can be removed to the sitting-room, where they will form a charming decorative group with Ferns and foliage plants. On the care of Lilies after blooming depends their future value, and those who wish to cultivate the same bulbs during the following season must cut off the blossoms directly they fade, leaving both stems and leaves to die away gradually, the pot being placed out-of-doors in a sunny situation and supplied with water as usual, though not so frequently as when in full growth. Directly the last of the foliage is dead the Lily should be given a shift into a pot two sizes larger and treated in the same way as when it was first procured.

I. L. R.

Spiraea palmata.—This *Spiraea* is so beautiful in masses and by the waterside that it should be made careful note of by all who have streams, ponds, or lakes which are left unadorned by flowers at their margins. It is one of the finest of all hardy plants, but seldom put to its best use, which is for fringing the margin of lakes. Under good treatment it grows nearly or quite 4 feet in height, proving quite hardy, and enjoying heat a rich, well-manured, foamy soil. I wish to bring out in particular its usefulness for the edges of water, but it may be naturalized in the wilder parts of the garden, where, if grown in large groups, the effect of its crimson flowers is distinct and attractive. It is a pity to grow such a fine hardy plant so largely in pots and neglect it in the garden proper, to which it is capable of giving much beauty.

Cycas revoluta as a room plant.

but the best thing is to cramp them at the roots, than they can remain in the small pots. The best of the Cycads are the *Encephalartos* and *Macrozamia*s.

GLADIOLI FOR A ROOM.

THESE splendid flowers have been so wonderfully improved of late years by hybridisation that few plants can now compare with their magnificent colouring and large flowers, borne on stately spikes. The newest variety of all, *Gladiolus Nancieanus*, raised by M. Lemoine, of Nancy, being a distinct type, with blossoms from 5 inches to 6 inches across, each bearing volupty blotches of rich and often contrasting colour on two of its petals, the flowers being borne on branching spikes in great profusion. These Gladioli are as hardy as the old *gandavensis* section, living out-of-doors in a sheltered spot; but they are especially suitable for pot-culture, as their fine blooms open even better in the room than in the garden, where the hot sun is apt to fade the lower blossoms before the upper flowers are open, which is not so much the case where a semi-shade is provided, so that the whole spike is open at one time. Nothing can be easier than their cultivation in pots, for they require no greenhouse, and no heat, the bulbs, which should be taken up from the ground in October, and kept in sand in a cellar or other frost-proof place until the end of February, are then placed singly, each in a pot measuring from 6 inches to 7 inches across (according to the size of the corm), placing careful drainage at the bottom, and using a light

(scarlet, toning to orange, with maroon spots), *Charles Ballet* (deep-purple, with white and maroon bands and blotches).—I. L. R.

LILIES FOR A ROOM.

THERE are no finer decorative plants than the Lilliums, and as those are so easily grown out-of-doors or in a frame, they should be seen much more frequently than they are in our drawing-rooms. It is not difficult to have a continuous supply of these splendid flowers from early spring till late autumn, and even in winter those who have a heated greenhouse may cultivate the beautiful White Trumpet Lily (*L. Harrisii*), which bears forcing better than most. Some of the finest in shape and colour are the speciosum family, *Lilium speciosum*, *rossum*, and *rubrum* being delicately tinted and spotted with clear crimson, while *L. speciosum Kretzeri* is a pure white Lily, quite silvery in effect, and very beautiful. The well-known *Lilium auratum*, the Golden-rayed Lily of Japan, is perhaps the most stately of the tribe, and this is fairly hardy, so that it can be grown in pots even by those who have no greenhouse. *Lilium tigrinum splendens* is another magnificent plant, tall and stately, with large orange flowers, handsomely spotted. This Lily comes in after the speciosum group are over, and can be had in bloom by retarding a few late specimens till November. Perhaps the following list of some of the best Lilies for pot cultivation may be of use in their order of flowering. After the lovely *Madonna Lily* (*L. candidum*), may be

RULES FOR CORRESPONDENTS.

Questions.—Queries and answers are inserted in GARDENING free of charge if correspondents follow the rules here laid down for their guidance. All communications for insertion should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR of GARDENING, 37, Southamption-street, Covent-garden, London. Letters on business should be sent to the PUBLISHERS. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Unanswered queries should be repeated. Correspondents should bear in mind that, as GARDENING has to be sent to press some time in advance of date, they cannot always be republished in the issue immediately following the receipt of their communications.

Answers (which, with the exception of such as cannot well be classified, will be found in their different departments) should always bear the number and title placed against the query replied to, and our readers will greatly oblige us by advising, as far as their knowledge and observations permit, the correspondents who seek assistance. Conditions, soils, and means vary so infinitely that several answers to the same question may often be very useful, and those who reply would do well to mention the localities in which their experience is gained. Correspondents who refer to articles inserted in GARDENING should mention the number in which they appeared.

4254.—Roses in small pots.—Will H.P. Roses grow and flower well in 6-inch or 8-inch pots?—P. R.

4255.—Cholera ternata.—I should be very pleased if some of your readers would give me particulars about this shrub?—R. C. S.

4256.—Myrsiphyllum asparagoides.—Please tell me how to grow this plant, and give also description of it, as it is quite new to me?—B. C. S.

4257.—Potignonette.—I should be obliged if you would tell me how to grow Potignonette in pots, like the market growers deal with?—D. D. AEROSTAT.

4258.—Herbaceous plants.—I should feel much obliged if you would explain what is meant by herbaceous plants, and indicate a few of the best and state flowering season?—H. F.

4259.—Carnation and Plectra-seeds.—I have had a packet of Carnation and Plectra-seeds sent me. Could I sow them now with any hope of their flowering next year?—H. F.

4260.—Strawberry border.—I shall be greatly obliged if any of your readers will give me directions for laying down a new Strawberry border, also hints on their culture?—STAMP.

4261.—Vines in pots.—I have some young Vines in 7-inch pots, which were struck the beginning of this year. Should they be potted again; or will they fruit in such small pots?—L. M.

4262.—Grapes splitting.—What is the cause of Grapes splitting? I have a Gros Colman Vine in a pot, and some of the berries as they begin to turn colour are splitting.—L. M.

4263.—Show Roses.—What are the best twenty-four H.P. Roses for show, and how should I prepare them for exhibition? Also the best twigs for pot culture? What manures do Roses require?—P. A.

4264.—Rose Fortune's Yellow.—I have a Rose Fortune's Yellow which grows well but does not flower. Does it require any particular treatment? It has a south aspect, and is trained up a verandah.—A. W.

4265.—Stephanotis floribunda.—I should be much obliged if anyone would give me some information as to a plant of Stephanotis which is showing fruit. Is this a rare occurrence in this country, and is the plant edible?—P. McLEARN, Ireland.

4266.—Frogs.—I shall be glad of any information about spawn from the small tree frog? I have a saucer of it in my greenhouse. I am anxious to know what food and treatment the tadpoles require and when they develop into green frogs?—C. B. S.

4267.—Christmas Roses.—Will someone kindly tell me whether I could grow Christmas Roses in a London garden to bloom in Christmas or in a conservatory (north-west aspect), and what would be the treatment? Locality, Kensington.—E. R.

4268.—Melons.—I am trying to grow Melons, and although my plants are quite healthy I find when the fruit gets about the size of a large Gooseberry they begin to rot at the eye. I am quite an amateur gardener, and shall be glad of advice.—A. C. PERRINS.

4269.—Destroying Nettles.—How can I get rid of a quantity of Nettles which have been growing for years in a bed of Rhododendron? I have tried to pull them up, but they grow again directly. I do not want to disturb the Rhododendron.—INEXPERIENCE.

4270.—Manure.—Being short of ordinary manure, would your correspondents kindly inform me what is the best artificial to use for kitchen garden purposes? Can one use Peat-Moss-litter from the stables with any good results? I should add soil fairly light.—J. N. B.

4271.—Border of Roses.—I have a border which has been utterly neglected and is very old, the good Roses having died and the Manetti stocks grown up nearly 6 feet. What is the best thing to do, to cut them back for bedding or throw them away and plant afresh?—NAPOLI.

4272.—Cutting back Hollies.—I have two clipped Holly-trees about 20 feet high, which are too close to the house and rather obtrusive in growth. I should like to cut about two-thirds of them back. Can this be safely done, and at what period of the year?—JANUAR.

4273.—Clematis attacked by mildew.—Some, but not all, the Clematises on front of my house, facing south, are suffering from mildew. A fine old Wistaria is trained along the south front over them. Can this be in any way the cause of the same?—AN OLD GARDENER.

4274.—Neapolitan Violets.—Will anyone tell me the best thing to do with Neapolitan Violets that were brought from Milano last spring and planted in the open

and died away during the great drought? They are now pushing up young leaves. Should I put them in a frame to ensure blooms?—NAPOLI.

4275.—Tomatoes curling up.—I should be obliged if anyone will tell me why the leaves of my Tomatoes in greenhouses are beginning to curl up! There is a good lot of fruit on the plants, plenty of root-room, and they have had proper quantity of water. The lower leaves are all pinched back to the first joint.—E. GAZZ.

4276.—Best Self Carnation.—I am pleased to find the cause of the Self Carnation advocated in GARDENING. "A. H." would confer a favour on many of your readers by giving the names of a dozen or more of the best selfs for the garden. They must be non-bursters, of robust habit, good form, and colour.—R. T. L.

4277.—Clematis dying.—Two fine purple Clematises of mine appear to have died this year. They grew splendidly and were covered with blooms, and just as they (the blooms) were about to open they suddenly began to wither and died rapidly, for no reason that I can discover. Can anyone explain this or tell me what to do in the future?—C. S. O.

4278.—Building a Tomato-house.—I am going to build a lean-to Tomato-house. How wide and how deep should the bed be? I want to get large fruit. Should the leaves be stopped at a joint or let to grow? I have some fruiting plants in small pots, and some in larger pots; they are not doing so well as those in small pots. I keep all side-shoots out?—CONSTANT READER.

4279.—Rose Reine Marie Henriette.—I purchased the above Rose this spring, and planted it in a cool greenhouse border. It made four or five shoots about 3 feet in length. What should be done to these as regards pruning? Should they be trained in at full length, or should they be cut back? If so, to what length and when? Also is this a good Rose for such a house?—EMIN.

4280.—Early Strawberries under glass frames without heat.—In the place I am taking at Mitcham I shall have a south-west slope, and think Strawberries would do it. What is the best sort for early treatment in this way? When should plants be put in, and when should frames be put over them? Is there any advantage in using pots in preference to planting in ground?—ASH VALM.

4281.—Vines in cool-house.—I have three Vines in cool-house, and some time ago something took the foliage and began to turn them yellow. The leaves looked scorched. I regarded it as red-spider, so I began to syringe every night with clear water, and have done so until now. Should I keep on syringing them now, as the fruit is beginning to colour? What should I do to the Vines when the fruit is off to cleanse them thoroughly.—H. W.

4282.—Laying out a garden.—I have an acre of land in south Durham on which I have built a house, and would be very grateful to you for advice as to the best and most profitable way to lay out the garden for fruit, best kind of trees and bushes to put in, distance apart, time for planting, &c. The land is about 10 miles from, and 100 feet above, the sea. It is away from smoke. Soil is rich and sandy 18 inches thick, with a sand-bed underneath.—J. R., Middleborough.

4283.—Heating frames.—I am going to heat five brick frames, which are in a row touching each other. Total length and width, 50 feet by 7 feet. I should be greatly obliged if any of your readers will kindly tell me the best boiler to get, and whether I ought to use 4 inch or 2-inch pipes? I want the frames for Cucumbers and for raising bedding plants. I should like to be able to keep up a heat of 60 degs. in winter at night. Should like to know the cost of heating same and the best firm to go to?—E. GAZZ.

4284.—Pontry destroying garden.—Being an old reader of your paper I venture to ask your advice. I have a small garden, and being a great lover of flowers, I spend all my spare time among them; but my neighbours keep poultry, which are always tearing everything to pieces, and no matter how much I complain it still goes on. As last I gave notice I would kill all I found on my place, but they say I will have to pay damage. Could you tell me if I may kill, or what course I should take?—J. C. JONES.

4285.—Old Vines.—What is best to be done with old Vines? They are about sixty or seventy years old at least, and have been badly managed several years back. They were formerly grown on the long-rope system, but are now in a very confused state. In places, several feet of old canes are blind. The borders also in a very bad state and sour. I am in favour of cutting out old Vines and planting young ones, but my master thinks lifting, root-pruning, &c., would do. They can have very few roots in a sodden border.—T. H.

4286.—Treatment of fruit-trees.—I have some young Peach and Apricot-trees growing in my garden trained on to the wall. They are making a lot of young shoots, some about 1½ feet long. I should like to know how to treat them? Should I cut them back to induce side-growth to keep the tree well furnished from the bottom, or should they be all trained in at full length? The strong shoots of this year's growth on the Peach-trees are throwing out side-shoots near the top, and I am afraid if they are left their whole length that the tree will get bare underneath.—EMIN.

4287.—Eucalyptus globulus.—I have three plants of Eucalyptus globulus, about 4 feet high above the pots. They were reported about five weeks ago and are growing well. They are now outdoors, with the pots sunk in the ground. In winter they will have to stand in a greenhouse facing nearly south-west. I want to dwarf them and make them more bushy. Please advise me as to its treatment, soil, &c. Can they be grown from cuttings or only from seed? The above plants were raised from seed and were neglected in their early growth. I want to get a few dwarf plants from them.—A CONSTANT READER.

4288.—Ivy on walls.—What course is to be taken from walls instead of clinging to them as usual? Round my house in North Cheshire I have a number of Ivies, including Emerald Gem, Angularis aurea, Caswoodiana, and Margaria argentea. These are planted on north, south, and west walls, built with ordinary bricks and mortar. All these plants are strong and healthy and in vigorous growth, but the shoots, although well supplied with suckers, curl

from the walls. My gardener carefully nails them up, but allow about another 6 inches of growth they again curl away and twist into knots.—LIV.

4289.—Odontoglossum nebulosum.—Will you tell me when O. nebulosum should flower? In "Williams' 'Orchid Grower's Manual'" it says "with the new growth." Does this mean like O. citreolum, and if so is similar treatment necessary, keeping it dry till the spikes appear? I have O. citreolum and always flower it well, but am not successful with O. nebulosum. I have two or three mature pieces which are in the best condition and made good growth for two years, but have not bloomed. This year's growth is now advanced, but I have seen no sign of flower. I grow them cool. Advice will be much esteemed.—T. P. WARREN.

4290.—Mealy-bug on Vines.—I have four young Vines (Black Hamburg and Madresfield Court) in their second year of bearing fruit which are badly infested with mealy-bug. The bunches are so infested with the white fluffy insects as to necessitate each berry being cut off and wiped. The joints and shoots of the Vines also show the bug. Last year each Vine was allowed to carry two bunches, and they were affected in a similar manner, but in a less degree, and after the leaves decayed the bark was peeled off and the stems dressed with Gishurst compound once, but nothing more was done. Is there any certain cure, or will it be advisable to take out the Vines and plant others?—SUBSCRIBER.

4291.—Tomatoes.—I have some Tomato-plants growing in 12-inch, 11-inch, 10-inch, and 9-inch pots respectively on the front shelf of an unheated lean-to greenhouse, south aspect. They are growing vigorously on single stems, and have about six trusses of fruit and bloom on them, but none ripe, and the top ones are not set. Would these plants bear well and the fruits ripen if I train them up the roof, or should I stop them? Also should the blooms be thinned out? I water them once a day with liquid-manure alternately, and syringe them two or three times a day. I close the house at night, giving a little air top and bottom. I have given them a top-dressing once. Is my treatment right?—CONSTANT READER.

4292.—Cutting Yews.—I should be much obliged if someone would answer a few questions as to the best method of cutting Yews. First, as I am most anxious to plant some in an old formal Jacobean garden. I suppose I bought a number of well-grown, bushy plants, of say, 4 feet in height, would it be possible to cut them into any simple shapes, such as pyramids, large balls, cubes with ball tops, and so forth, and, if so, how should I set to work? Should they be cut at once, and as they grow kept trimmed into the shape required, or would it be better to leave them entirely untouched until they have grown to the necessary height, which would be from 6 feet to 7 feet? Of course, in pursuing the latter course one would be obliged to cut into and remove a lot of old wood with no foliage on it, and I should like to know if the bald patches thus made would be green next year?—K.

To the following queries brief editorial replies are given; but readers are invited to give further answers should they be able to offer additional advice on the various subjects.

4293.—Petunias (F. J. F.).—The Petunias are not uncommon, although rarer than many other kinds. They are of no particular value.

4294.—Mildew on Roses (C. W. Vincent).—Your Roses are affected with mildew, from which very few varieties are quite free. Dust the leaves with flowers of sulphur, which is an excellent remedy.

4295.—Manuring flower-border (Beginner).—Mulch the border with well-decayed manure and lightly fork it in; but unless the border is really impoverished it is best to leave it alone, as the plants are likely to get much disturbed, if not killed, unless great care is taken. Do this work before planting the bulbs.

4296.—Unhealthy Maiden-hair Fern (A. C. P.).—It is evident that the roots are wrong. Perhaps the plant requires re-potting. If so, repot into a mixture of loam and peat. Drain the pots well and water carefully. Should be done at a time after potting. Too much moisture or old country air would also make the young fronds go in the way described.

4297.—Dahlias eaten (Briarwade).—Judging from the flowers sent, asparagus are responsible for the mischief. Put a small flower-pot, with a little hay in the bottom, on the stake, and the pests will crawl into this at night. In the early morning they can be easily captured. Bees-sticks placed about amongst the leaves form also a very good trap; but the flower-pots are the more reliable.

4298.—Roses (Puck).—We have inserted some of the queries under the proper column. You could grow Roses well in a bed facing south-west; good, well-manured, deep soil is the best for the plants. You will get as much information from GARDENING as anywhere; ask questions when you are in doubt. The time to plant Roses is October or November. They must not be out about.

4299.—Red-spider (Anxious).—The last enclosed shows that your Vines infested with red-spider. You have kept the roots too dry and not ventilated the house properly. Give water more freely, and the house must be kept moist, so that your plants will have no cause to fear pest. We should syringe walls with clear water. Put water on the pipes and also dust the leaves. Persevere with these remedies. For the other, hang a few rather arrow-headed nettles about filled with syrup or some sweet substance. This is found an excellent trap.

4300.—P. opogating "Geranium" (Mrs. Scott).—"Geranium" may be struck now. Cut the shoots just under a joint, and insert in a pot or box filled with light soil. They will strike either in the open or in a greenhouse. Do not give too much water. Put a few crocks in the bottom of each pot. Bulbs may be kept in boxes through the winter; store them when quite dry. Frost must not reach them; select also a cool place. October is the best month for bulb planting for spring; or late in September. Order what you require at once. See article on bulbous flowers in GARDENING, July 29.

4301.—Growth of Dext-moth (W. A. Bois).—The growth you sent are the caterpillars of the Dart-moth (Agrotis segetum). They all had legs; I could not find

one without them. They are very difficult, or rather troublesome, to destroy, as any insecticide loses its strength in soaking through an inch of soil; but watering with soapy water is useful, as it brings the insects to the surface, when they can be picked up by hand. The soapy water must be freely used, honing round the plants, as turning the plants out of their shelter in any other way, and picking them up is the most practical plan.—G. S. S.

406.—Sand wasps (No Name).—The wasp-like insect you sent me one of the sand wasps (*Mesochorus arvensis*); they are very useful insects, as they destroy a great number of flies, and had evidently come into your room in search of them. These wasps make their nests in sandy banks and similar dry places; they fill the cells, of which the nest is composed, with dead flies. An egg is laid in each cell; when the young grubs hatch from these eggs they find themselves surrounded with an ample supply of food. These sand wasps, of which there are many kinds, should never be destroyed, for the number of small insects which they destroy is very large. Some species collect web silks, others aphides, others spiders, and so on.—G. S. S.

NAMES OF PLANTS AND FRUITS.

*. Any communications respecting plants or fruits sent to name should always accompany the parcel, which should be addressed to the EDITOR of GARDENING ILLUSTRATED, 37, Southampton-street, Strand, London, W.C.

Names of plants.—J. Burden.—1, *Chenopodium rubrum*; 2, *Trifolium maritimum*; 3, *Glucium luteum*.—C. Wilks.—1, *Lithochrois leptophylla*; 2, *Anemone adianthifolia*; 3, *Microlepis coehra*; 4, *Diplazium decussatum*; 5, *Onoclea sensibilis*; 6, *Anchitaea virginica*.—C. E. F.—1, *Sabbiosa arvensis*; 2, *Hieracium aurantiacum*; 3, *Hieracium pilgeri*; 4, *Salicaria dubia*.—David G.—1, *Acideta densa*; 2, *Cattleya Gaskelliana*, ordinary form; 3, *Odoothlogium grande*; 4, *Cattleya Bowringiana*.—C. Young.—1, *Saccolabium Bismar majus*; 2, *Cattleya Schottfeldiana*; 3, *Laelia elegans*.—T. Herriott.—1, *Dendrocaulis adiantoides*; 2, *Lomaria discolor*; 3, *Asplenium lucidum*.—H. Cottam.—1, *Armeria vulgaris*; 2, *Stachys sylvatica*; 3, Send again. —H. Rowlett.—Cannot name such miserable bits and without numbers. —G. Bickley.—1, *Cattleya Bowringiana*, a very good dark form; 2, *Cattleya granulosa*.—H. Foster.—1, *Phaiolopsis antiferre*; 2, *Mitella Morellana*; 3, *Laelia Schilleriana*.—Erin.—Please send specimen; cannot name from mere description. The Periwinkles are evergreen. —A. K.—*Clethra alnifolia*.—Dick.—1, *Veronica speciosa*; 2, Please send in flower; 3, Next week. —E. M. E.—We cannot distinguish the substance from seaweed; such things occur so near the sea. Perhaps seaweed has been used in or near the garden for some purpose. It is best not unduly. —Max Hartlett.—We are sorry that the flower sent was shrivelled. Please send another specimen. —H. Hughes.—*Maxillaria sp.* —H.—*Delphinium albiflorum*.—T. Hill.—The white one is *Galage officinale alba* (the White Goat's Rue); and the crimson one, *Oewego Tea* (*Monarda didyma*). —Dolgray.—*Rosa Caucasia*.—No Name.—1, *Double Snowwort* (*Achillea ptarmica* f. pl.); 2, *Cuscuton Ephebra*; 3, *Astragalus major*; 4, Next week. —F. A. S.—Cannot tell from a single specimen. It looks like *Mary Morris*. —F. M. H.—*Spermannia africana*, we presume, but you must send flowers; it is impossible to be certain of a name from leaves only. —S. C. Austin.—*Hibiscus sylvaticus* (the Syria Mallow).—T. W. Selby.—*Chilensis Yellow*.—Mrs. O'Reilly.—1, *Rudbeckia californica*; 2, shrivelled; 3, next week; 4, *Bocconia cordata*; 5, *Dicentra eximia*; 6, *Tropaeolum coccineum*. —Names of fruit. R. B.—1, *Apple Grovendale*.—H. E.—1, *Calluna*; 2, *Burberry Pippin*.—Rev. E. C. Diaz.—*Apple Herwarden*.—Spice.—*Apple Irish Peach*.—Mrs. O'Reilly.—Apparently *Strawberry Pippin*, but it may be some local kind.

TO CORRESPONDENTS.

We should be glad of readers would remember that we do not answer queries by post, and that we cannot undertake to forward letters to correspondents, or insert queries that do not contain the name and address of sender.

Horberry.—We do not know of such a work. —Stamp.—We do not recommend any special trader. —J. Shering.—Please send fruit; it is impossible to tell the name of the variety from leaves only. —J. G.—Please see answer to "Stamp." —Mrs. Scott.—A volume of GARDENING will answer as well as any manual for amateur gardeners. We shall be pleased to answer any questions. See short Editorial Replies. —G. C.—See the advertising columns. We do not recommend any special matter, but they differ greatly. —Some of the *Amaryllis* are sweet, but they differ greatly. Keep the bulb by all means. —H. J. Tomlin.—Please see advertising columns.

GREENHOUSES.—Portable, 7 by 5 ft., span-roof, 64s.; lean-to, 41s. Span-roof forcing-house, 20 by 9 ft., £9 10s. Garden frame, from 17s. Garden lights, from 3s. The above are all complete and packed on rail. State size required, and send for illustrated Price List free. J. JAMES, 355, High-road, Chiswick. Inspection invited.

TANNED GARDEN NETTING.—Elastic Netting, Tinsley Willendon Rat-proof Scrim and Cloths, Archaengal Mats, Ruffs, Garden Tents, Flags, Bink Cloths, &c. Send for samples and prices to JOHN KINGDON & CO. 19, Long-lane, West Smithfield, London, E.C.

NETTING for Tennis Bordering.—Good colour and specially prepared, with line attached to net, top and bottom, throughout. Easy to erect or to take away. 25 yards long, 3 yards wide for 1s. 6d., carriage paid.—HY. J. GABSON, Net Works, Ry.

SCOTT'S WASP DESTROYER has stood many years' test as the only effectual protection for Fruit Trees, &c., from Wasps and Flies. Prices 1s. 6d. and 2s. 6d. per bottle. Sold by all Nurserymen and Florists.—Makers: CORRY & CO., Limited, 13, 15, and 16, Finsbury-square, London, E.C.

THE GARDEN GUN.—Fires bullets, shot, or darts. Kills birds, rabbits, &c. No powder or license required. Price 2s. 3d.; extra powerful 3s. 6d. Carriage paid, from inventors—JOHN BUCKLEY, 15, Strand, London, W.C.

G. HAYWARD F.R.H.S. CRYSTAL PALACE HORTICULTURAL WORKS, 20, FOXRERRY ROAD BROCKLEY, LONDON.

This is Hayward's No. 1 and No. 2. No. 1 Span-roof and No. 2 Lean-to Greenhouses are prepared especially for amateurs, made of Best Red Deal, thoroughly seasoned, complete with Ventilators, Door, Stages for plants, Painted on cast-iron, Green, and economy iron-work. Delivered and packed free on rails at the following prices, satisfaction guaranteed. Write for New List.

No. 1 Span-roof. 7 ft. long 6 ft. wide £3 18 0. 10 ft. " 8 ft. " 4 0 0. 12 ft. " 8 ft. " 0 0 0. No. 2 Lean-to. 7 ft. long 8 ft. wide £2 8 0. 10 ft. " 8 ft. " 0 0 0. 12 ft. " 8 ft. " 0 0 0.

For other class and prices write for Illustrated List to G. HAYWARD, BROCKLEY, S.E.

JONES & ATTWOOD. IRONFOUNDERS, STOURBRIDGE. DESIDERATUM HEATING APPARATUS. For Greenhouses, &c. Catalogue free. Jones' Treatise "Heating by Hot-water," 130 pages, 6d. engraving cloth.

ORCHID PEAT. PREPARED ready for use and in blocks; also RHODODENDRON PEAT, PEAT MOULD, LEAF MOULD, LANA, and POTTING COMPOST. For Price List apply to The Forester, Jordan Wood, Hoxley, Kent.

TENTS! TENTS!! TENTS!!! Suitable for Gardens, Cricket, or Camping-out purposes. Forty feet in circumference, pure linen, with pegs, poles, and lines complete. These tents are white, and have never been used a little by Her Majesty's Government, and cost over £2 each. I will send one complete for 30s. Can be sent on approval. H. J. CASSON, Government Contractor, RYE, SUSSEX.

THE STOURBRIDGE HEATING APPARATUS. Consisting of Independent, Slow Combustion Boiler with damper, 18 ft. of 4-inch pipe, supply system, 6 ft. smoke pipe and joints complete for fixing. Price, delivered free to any railway station in England or Wales £2. Illustrated Price List of hot-water-pipes, &c., free on application.—J. & W. WOOD, Birmingham St. Foundry, STOURBRIDGE.

DON'T FORGET!—The Patent Invincolite Crook for plant-pots keeps out worms and all vermin; saves time, expense, and annoyance; fits any pot; lasts for many years; will be used in every garden when known. 30, 1s.; 100, 3s.; 1,000, 25s., free.—A. PORTER, Stone House, Maidstone.

PEDIGREE SUSSEX OATLE (Gravetye Herd).—The Sussex cattle are growing steadily in public favour, both in this country and in America, where a few years ago a steer of this breed won the first honour in the book test at Chicago. Choice sows and Yoo or stock of the best blood for sale. This herd never got up for show, but kept under the most natural conditions possible. Inspectors East Grinstead, Sussex. Address, BAILIFF, Home Farm, Gravetye Manor, East Grinstead, Sussex.

TIAMWORTH RED PIGS.—For Sale, Sows, Yells, and Young Boars. Pure pedigree bred. Recommended as good bacon pigs; also for crossing. Particulars from BAILIFF, Home Farm, Gravetye Manor, East Grinstead, Sussex.

SOUTH DOWN SHEEP.—Pure bred SHEEP, from flocks of best blood, for stocking or exportation. A number of good rams.—Address, BAILIFF, Home Farm, Gravetye, East Grinstead, Sussex. Inspection invited.

GREENHOUSES, Cheapest and Best.—Lean-to, complete, from 46s. Span-roof, 5s. Strong Garden Lights, painted and glazed, 4 by 3 ft., 6s. each; 6 ft. by 4 ft. 6s. 6d. each. State sizes, and obtain estimate free.—SHEPHERD & SON, Daventry-road, Shepherd's Bush, London. Catalogue post free.

TO BE SOLD.—200 pieces Tiffany at 1s. 3d. 1 piece, about 20 yards each.—JOHNSON, 7, Park-lane, Liverpool.

WANTED, a copy of Robinson's "WILD GARDEN," 1st, 2nd, and 3rd edition, all or any. Send particulars as to price, 2s. to T. SPANISH, 57, Southampton-street, Strand, W.C.

EVERYONE WHO HAS A GARDEN, GREENHOUSE OR WINDOW BORDER SHOULD READ A PAMPHLET, POST FREE.

HOW TO INCREASE THE FRUITS OF EARTH.

By G. H. WITH, F.R.A.S., F.O.S. Trinity Col., Dublin. Contains full particulars of very remarkable discoveries relating to Plant Life. Shows how crops of vegetables may be largely increased, lovely flowers grown to perfection, and fruit-trees made to bear in abundance. Selections from Hundreds of Testimonials. Post free from JAKEMAN & CARVER, Printers, Hereford.

With nearly 700 Illustrations, 15s., post free, 15s. 6d.

THE Vegetable Garden

Illustrations, Descriptions, and Culture of THE GARDEN VEGETABLES

Of cold and temperate climates.

London: JOHN MURRAY, Albemarle-street, And all Booksellers.

FIFTH AND POPULAR EDITION. Price 1s.; post free 1s. 3d.

HARDY FLOWERS

Giving descriptions of upwards of 1,300 of the most ornamental species, with directions for their arrangement, culture, &c.

London: 37, Southampton-street, Strand, W.O.

"Gardening" BINDING COVERS.

Covers for Binding each Volume of GARDENING, from Vol. 1. to present time, are on sale, price 1s. 6d. each; post free, 1s. 9d. each. Of all Booksellers or Newsagents, or from the Publishing Office, 37, Southampton-st., Strand, W.C.

£1—SURREY HILLS, beautifully timbered FREEHOLD BUILDING or GARDEN PLOTS, 20 by 150 ft., £10 each. 50 by 200 ft., £25 each. Possession on payment of 10 per cent. deposit. Balance by 12 half-yearly instalments. Only a few plots remaining unoccupied. Return fare, Sunday, 1s. 9d. Plans—BROUGHTON, Westerham.

BECKENHAM, KENT.—To be sold privately, a DETACHED BIJOU RESIDENCE, suitable for a moderate-sized family; situate on high ground, overlooking on one side an extensive park, studded with fine old timber, and on the other commanding fine views in the direction of Forest-hill and Hydenham. The grounds, of about 12 acres, are well laid out and planted with choice trees and shrubs. The tennis lawn is large, and the kitchen garden productive and well stocked with fruit-trees. The house is substantially built, the reception-rooms lofty and well proportioned, with convenient domestic offices on ground floor. There are 10 bedrooms, four seven bedrooms, dressing-room, bathroom, &c. Good stabling for three horses, coach-house, poultry-house (with rail, gardener's toolshed, &c., &c.). The property is held for a term of about 70 years, at a nominal ground rent of £4 10s. per annum. Particulars from A. M., care Editor, 37, Southampton-street, W.C.

BEAUTIFUL COLOURED PLATES of FLOWERS

FOR SCREENS AND SCRAP BOOKS.

From Drawings by the best flower painters, finely reproduced in colour. Per dozen, 2s. 6d.; per twenty-five, 5s.; per fifty, 9s.; per hundred, 15s.; post free. Well assorted or customers' own selection. Set of 400 (each different), £3, post free. P.O. to T. SPANWICK. Specimen Plate, post free, 3d.

ROSES.

MANURES FOR ROSES.

Now that the planting season will soon be here, a few notes upon the manures most suitable for Roses may be welcomed. I am certain that many soils have been injured as far as the Rose is concerned by injudicious applications of a manure that was unsuitable. For example, if the soil is naturally hot and dry, or of a sandy and porous nature, I would advise you to use neither soot nor guano. These have a great tendency to dry the soil yet more, and it is only in stiff and strong soils that they are really beneficial. On land of the last-named character these two manures are not to be despised. When planting Roses upon light and dry soils, such as is now under notice, it will be much better to use some cooling manure, and also one that will retain moisture. I would recommend a mixture of well-decayed cow-manure and stable-manure. If these are thoroughly rotted and turned over a few times they will benefit such soil more, and in a far more permanent manner, than soot or guano. A little agricultural salt incorporated with any mixture applied to very light land is decidedly beneficial. I well remember once having a large bed of Roses upon the site of some Asparagus beds that had been frequently manured with salt. These plants grew away more freely and later during the following summer than some upon the opposite quarter and where no salt had been applied. Used carefully, salt is an excellent and cheap manure: it keeps the soil cool and moist. I am a believer in the benefits accruing from a thorough mixture of manures, but if tied to one manure for Roses and upon an ordinary soil I should unhesitatingly choose pig-manure. This is very powerful and lasting, and if lightly forked in when used as a top dressing, or a few ashes be mixed with it before application, the unpleasant odour will be neutralized. Some apply lime and night-soil to this manure, but these disseminate so much of the valuable ammonia that I always use ordinary soil or ashes. Night-soil can be put to no better use than treading it well into the ground when forming a rosery. Here its fertilizing and lasting qualities will be seen for a long time, and when dug in no unpleasant odour results. Woollen-waste is a very useful manure for stiff soils of a clayey character. I have found it a very cheap and lasting manure. Fish-manure, on the other hand, is very evil-smelling and powerful, soon exhausted, and by no means cheap except in a few favoured localities. For general work, a mixture of decayed cow and horse-manure is the best. This should be turned over frequently, so as to avoid any white and drying heat in the centre of the heap, and also to secure all the moisture from urine or rain. Bone-meal is an excellent artificial manure. Roses are hungry plants, but they want steady and constant feeding to secure good growth and flowers; not excitement, with its consequent sappy growth, followed by a relapse through the soil having been impoverished with artificial manures. Bone-meal, however, with woollen-

waste, rags, swoopings from the shoeing-forge, &c., mixed in small quantities with thoroughly decayed manure, will suit all soils equally well and form a good mixture for Roses. P.

4383.—**Rose Reine Marie Henriette.**—I will answer the latter part of your question first, by saying that the above Rose is by far the best red variety for a greenhouse that I am acquainted with. It invariably comes a good colour under glass, while it is one of the finest blooming climbers we have, and produces most handsome foliage. Train in your shoots at full length, and when they have flowered in the spring remove the older growth, and encourage more long rods to form. These will probably reach double the length next year, and provide a proportionate quantity of bloom.—P. U.

4375.—**Border of Roses.**—Probably the Roses have been growing where they are for many years. If so, dig the lot out in November, and trench the ground, adding a liberal dressing of rich farmyard-manure. Pig-manure is also good for Roses. Select all the plants that are good enough to be replanted, throwing the stocks away, and any Roses that are quite worn out. Some good decayed loam or rich soil from another part of the garden ought to be placed around the roots. Some of the better Roses should be purchased to make good the losses that have been sustained. Roses do far better when they are removed and replanted every second or third year.—J. D. E.

4368.—**Rose "Fortune's Yellow."**—Your plant is in a favourable position, and as it is growing well it should also flower satisfactorily. Perhaps you make the mistake of pruning it. Strong growing Roses are more often than not spoiled by injudicious pruning. Let your plant grow just as it likes, and do not touch it with the knife, except to remove any wood that may have got killed by frost in the winter. There is nothing prettier than this Rose when allowed to grow and bloom at will.—P. U.

—This Rose does require great care in pruning, but in other respects it thrives under the same conditions as other Roses, when the position is warm enough. On the south front of Colonel Sorle's house at Fitzroy, Taunton, it succeeds admirably, and last year, from the end of March to the end of April, produced hundreds of fine blooms. Indeed, I never saw this Rose in such good condition before in the open air. With regard to the pruning, quite two-thirds of the shoots should be cut out directly the flowers are over, and in the case of a weak plant, all the growth made during the summer should be nipped or tied in. If, however, the young growth is crowded, the weak shoots should be thinned out at the end of September. If your plant does not flower under this treatment you may safely conclude that the position is not warm enough to ripen the wood.—J. O. O.

4367.—**Show Roses.**—As you do not name any particular class of Roses, and as it is easy to select twenty-four good exhibition varieties from both the Hybrid Perpetuals and Tea-rose divisions, I propose choosing twelve from each.

Hybrid Perpetuals: A. K. Williams, Charles Lefebvre, Horace Vernet, Mrs. J. Laing, Alfred Colomb, Victor Hugo, Marie Beaumont, Dupuy Jamain, Camille Benardin, Louis Van Houtte, Her Majesty, and Duke of Edinburgh. Twelve Teas: Maréchal Niel, The Bride, Catherine Mermet, Souvenir d'un Ami, Perle des Jardins, Comtesse de Nadallac, Anna O'livier, Mdam. Hoeta, Jean Ducher, Niphetos, Innocente Pirola, and Françoise Krüger. The secret of getting good exhibition blooms is to secure sound growth without coarseness, and to keep the side buds thinned away from the main bloom as soon as ever they can be handled. Twelve good pot Roses are included in the following, the main colour of which are given: Niphetos and Souvenir de S. A. Prince (white); The Bride and Innocente Pirola (creamy-white), Angustine Guinoiseau and Madame Beaumont (blush); Madame Lambert and W. F. Bennett (red); Isabella Sprunt and Perle des Jardins (yellow), Madame Faloot and Sunset (orange and apricot), Souvenir d'un Ami and Catherine Mermet (soft-pink); Françoise Krüger, Jean Ducher, and Doctor Grill (salmon-buff).—P. U.

4358.—**Roses in small pots.**—With careful cultivation you may grow H.P. Roses successfully for several years in 8-inch pots, but it will be as well for you to understate at starting that everything depends on the kind of management the plants get, also on the selection of varieties. You will find some difficulty in keeping in vigorous health some of the dark-coloured Roses, such as Charles Lamb, Victor Hugo, and E. Y. Teas. At best they are indifferent growers. You will, however, find such bright-coloured Roses as Charles Lefebvre, General Jacqueminot, and Duke of Edinburgh answer your purpose admirably. Supposing the plants come to hand in the autumn established in 6-inch pots, let them be shifted at once into others 2 inches larger, and about Christmas prune all the growth back to the third eye. The subsequent treatment must be guided by the purpose for which they are required. If they are to be forced into flower early, they must be repotted every year early in August, having two-thirds of the old soil shaken away from the roots and fresh supplied. If they are to flower in an ordinary greenhouse temperature the repotting may be done in December. Earlier potting is necessary in the case of forced plants, as if the roots have not got a good hold of the new soil the plants will make growth, but give few flowers. If you want early blooms you had better not select such full-petalled flowers as La France and Violette Bouyer. Mrs. J. Laing is the type of flower you want, others equally good being Ulrich Brunner, Centifolia rosea, Mme. O. Luizet, Jules Margottin, and John Hopper.—J. O. O.

—Yes, the sized pot you name is the one generally used by market growers. All you want to secure is a fairly rich and loamy soil; to provide good drainage, so that plenty of water can be given while your plants are growing without making the soil stagnant.—P. U.

Sweet-scented Rose.—In article 4237 on Roses, your correspondent, "P. U.," while no doubt justly complaining of the behaviour of La France, says: "Though as initially scented, we can also qualify in this respect." Will be kindly if you will quote La France in particular.—J. L.

GARDEN WORK.

Conservatory.

Fuchsias planted out to the borders are still very beautiful with the drooping branches heavily laden with flowers. Plumbago zapensis (pink and white), are also forming a charming mass and will continue flowering until it is necessary to begin reducing growth to fit in light for the winter-flowering plants. Lillineum auratum and inoffolium, Heliotropes, and Petunias, add to the beauty and fragrance of the house. Tea Roses, when planted out, are nearly always in evidence, and when one has a roomy house to deal with, I like to plant out the roses and let them strike out. Myrtles are charming for filling in dark corners, either planted out in pots or tubs. Outlings of these and heads will strike oow; both of these plants will root in water. The other day I was in a handsome conservatory, and taking up a small bottle lying in a slanting position on the stage, I noticed it contained a Myrtle cutting with white roots, already formed in the water. This is a very simple way of striking outtings. The bottle was a small phial that would hold about an ounce of water. In this the Myrtle cutting had been dropped a month or so ago, and it was now ready for potting. One anything be easier or simpler? Other things, including flowers, might be rooted in the same way, but the success of the potting I do not after roots are formed the better. The time is close at hand now for potting up plants such as Salvia Eupatoriums, &c., which were planted out in spring to make growth. If the plants have grown strongly it will be better to pass the spade round them at oow, just to sever a few of the principal roots, so that when lifted the plants may feel less check. It is important when the potting up takes place that the plants should stand in the shade till new roots are formed, and the sooner the potting is made preparation for housing Azaleas and other things which have been placed in the open air. If Palms and foliage plants are left out outside long after the date, the leaves will be torn by the wind, and a disfigured Palm-leaf hangs on a long time. If Camellias are permitted to get dry now, the buds will surely fall. A little weak eot water will be good for them now, also for Azaleas and other things with pots full of roots, but the liquid-manure, whatever it is made from, should be used with care. No fire is required yet, and the lights may still be left open at night.

Stove.

The plants in this house will soon be worth looking at again. I think stove plants always show up best in the winter, when the days are cold, and the Polyanthus and Euphorbias are filling the house with a glow of scarlet. But there are still Rhododendrons to the stove. Allamandas, Dipladenias, Vines, Rhododendrons, and other things are still nicely in bloom. Anything tender to cold frames will soon have to be brought back to the stove, and in the meantime, cover the plants at night with mats. Water will be necessary now on cold nights, at any rate. Shading will hardly be required now. It will be better to give a little more air than shade overhead. The external air in the autumn is different to what it is in spring. It is warmer and has a ripening effect upon the growth. An effort should be made to clear out mealy-bug and other insects before winter, and the plants which have been taken out to recruit and ripen are brought back. Gardenias have been taken to the stove greenhouse to ripen growth. But when brought into the warm house again the insects will soon show their partiality for them unless they are cleared out now. There are insecticides that will destroy mealy-bug, if the mixture can be made to reach them, but there must be a peroxide of iron, and I am not in favour of peroxide or any other oil or spirit which is very powerful, and at the same time will not bleed with water. After all, the old remedy of soft-soap and water are equal, as is depicted in all insectaries where cleanliness carries weight. Insects of all sorts and sizes like to be quiet and peaceful.

Chrysanthemums.

There is a good deal of tlyng to do now; top-dressing opening out so that the growth may get formed a bit. Watering and other outlying details take up a good deal of time. The Chrysanthemum grower on a large scale has no leisure. When his is not watering or tlyng, he is altering the earthen pots, or taking the plants, or cutting the shoots, or otherwise carrying out necessary details that will bring success to the future. It is very important that the plants never suffer for the want of water. A good proportion of the strongest plants will require water twice a day in hot weather. Liquid-manure may be given twice a week.

Orchard-house.

Peaches and Plums from which the fruits have been gathered will be better placed outside now to complete the ripening. Orchard-house outtings to pots fit to well with the present manure for big Chrysanthemum bloom, as when the late Fuchsias and Plums are gathered the trees can be taken out, the house receive a clean down, and the Chrysanthemum can be taken in before frost comes. If any of the potted trees require larger pots the autumn, just as the leaves are ripening, is the best time to do it. Good sound loam, with a very little old manure, perhaps the manure may take the shape of bone meal. At any rate, a little enrichment of the soil is necessary on potted trees, even though rich top-dressings and liquid stimulants are used.

Cold Frames.

I dressy others are doing as we are in utilizing to the fullest possible extent the cold frames. Cyclotenus, Primulas, Chierarias, are daily demanding more room. Hence Begonias and soft things reared in heat, and which were brought out to ripen, have to be moved back to the greenhouse or stove. This space is required for striking cuttings of many things. For instance, I want to strike a lot of evergreen shrubs, and I must have frames for the work.

Window Gardening.

Fuchsias which have done flowering place outside to ripen. A few outtings of anything good may be taken. They will root now in a north aspect. Zonal Geraniums

alums* must not be overwatered. Keep Cutuses out in the sun a little longer; nut much water will be required oow. Pot a few early-flowering bulbs, such as early flowering Hyacinths, Scillas, Snowdrops, Tulips, and Narcissus. When these bulbs are kept long out of the soil they deteriorate.

Outdoor Garden.

Now very beautiful the common kinds of creepers—Ceanothus, Creepers, the Crimso Nasturtium, and others—are when trained past the stem of small trees, such as Laburnum, Theophrastus, Prunus laurocerasus, &c. They are especially useful in new places, where filling up stuff is peculiarly valuable. Another matter that might be noticed now is the value of annuals in large masses in oow gardens. Very few perennials will bear the pressure of thick planting for immediate effect, and neither is it necessary, as hardy annuals and roots of berdy herbaceous perennials can be bought cheap, and not only is the place furnished cheaply and rapidly, but most effectively where a little taste is brought to bear. Save seeds of good strains of annuals, biennials, &c., and put in cuttings of tender plants to produce stock for next year. The tender plants used for carpet-bedding, the Oleus, Alchoranthers, and Iresines, will strike oow if cuttings of the young shoots are taken, and planted in pots or boxes in a frame which is ventilated for about an hour every morning, and for the remainder of the time kept close and shady. Buds of roses and ornamental trees generally will take well now, as the late rains have made the bark work freely, and it is no use to attempt to bud unless the bark runs freely. It is full late to layer Carnations, unless the layers are to remain on the old plants till spring, and this late work I do not recommend.

Fruit Garden.

There is always more or less trouble with wasps in a dry, hot season, but the plague is worse than usual this year. If fruit is to be preserved a serious effort has doubtless been made in most places, and this effort will have to be continued till they are got rid of. Destroying the nests is the best course to adopt, to commence with the use of bottles half filled with beer and sugar. These bottles of syrup may be hung up anywhere where wasps frequent. Inside Vine borders must not be permitted to get dry, at any rate until the Grapes are perfectly ripe. Vigorous vines which are not over-cropped will continue to make laterals, and these should be removed when they can be rubbed off with the finger and thumb. The recent heavy rain will be a great help to the Apple and Pear crops, and if the wood and lollage of the trees are not too much crowded there should be fine crops of fruit. We have had a splendid time to make our Strawberry plantations, and after the exhausting summer more of the old plants than usual will be destroyed. Cherry and Plum stocks will work oow, as will also Apples and Pears. The Malice to durg-beds will require a little help from new dung. Careful watering and ventilation will be necessary, and if the canker makes its appearance over the affected part with fresh hot lime at once, and cover it as often as is necessary. The disease comes in the shape of a damp brown gangrene on the main stem. Remove runners from Strawberries to pots for next year's forcing.

Vegetable Garden.

Canillifers may be sown up to the end of the month in warm situations. If sown in a frame September will do. Another sowing of hardy kinds of Lettuce may be made to stand the winter, and this will pretty well complete the outside seed sowing for this season. Mustard and Cress will soon be sown under the shelter of glass—first, under handlights, and when the weather becomes cold in a warm house or Cucumber-house. Cucumbers for autumn or winter bearing may be planted now. Strong plants only should be used, and do not plant nearer than six feet. Winter Cucumbers are often raised by thick planting. Use only fresh, open, torily soil. The hills need not be large to start with, as fresh soil can be added oow. I always like, even when there are pipes for hot-water, to have a foot or so of manure over them, and for some years oow we have used the German Moss-litter manure, and never had better crops. Plant French Beans to warm pits for autumn bearing. This out the growth of Tomatoes in the open air, and stop at leaders, so that the whole crop may be expected. As for Chrysanthemum to pots, one may keep the water-pot going among them all day long, at least where a large collection is grown. The propagation of bedding plants ought to begin full swing; it is much the best plan to get plenty of outtings in good time, while the sun still affords plenty of heat, and get them well established before winter sets in. It has been getting all the "Geranium" outtings possible in the open ground, as I find they strike in this way with much greater certainty and less trouble than in pots or boxes; but it is getting rather late for this now.

Work in the Town Garden.

At the time of writing the weather is again extremely hot and dry, and watering occupies a large part of the time. Tomatoes in full bearing, especially when growing in pots or a limited quantity of soil, seem to take and indeed require almost unlimited supplies of moisture, under present circumstances, and though contrary to the treatment I usually advise, in our climate at least, I now find it advisable to damp down the house freely twice a day—morning and evening. The structure is, however, very light and airy one, and gets the sun all day long, while the ventilators are over entirely closed, eight or day, at this season, and there is not a trace of disease in consequence. "Geraniums" Fuchsias, Begonias, and other plants in full bloom to pots also require to be abundantly and frequently watered. Newly-layered Carnations also must be kept moist, and several kinds of bedding plants outside enjoy an occasional thorough soaking, when the time and water can be spared. As for Chrysanthemum to pots, one may keep the water-pot going among them all day long, at least where a large collection is grown. The propagation of bedding plants ought to begin full swing; it is much the best plan to get plenty of outtings in good time, while the sun still affords plenty of heat, and get them well established before winter sets in. It has been getting all the "Geranium" outtings possible in the open ground, as I find they strike in this way with much greater certainty and less trouble than in pots or boxes; but it is getting rather late for this now.

tings of Double Petunias, Heliotropes, Verbenas, Marguerites, and even Fuchsias, will root freely enough now in well drained pots or boxes of sandy soil, placed in cold frames, and kept moderately close, moist, and shaded. Bouvardias ought not to be potted any more oow, unless any of the shoots show for bloom, and this is not wanted yet, or they are wanted to flower very late, when the point of each shoot may be nipped out once more, not later than the end of this month. It is not of much use to keep the double-flowering kinds back so much, as they will not bloom at all freely after about October, so better let them go now, and retard the single varieties. The beautiful and fragrant E. Humboldtii corymbiflora also blooms naturally in the late summer and autumn, and must not be stopped any more. Finish layering Carnations, and keep all moist. Repeat Persian Cyclotenus, and keep them cool, moist, and in light shade. Obtain and pot a batch of Roman Hyacinths, and Paper-wives and other Narcisus for early flowering. B. C. R.

THE COMING WEEK'S WORK.

Extracts from a garden diary from August 20th to September 2nd.

It is making a good deal of growth, especially the Dijon Tass. Some of the long shoots of the standard plants have been shortened a little. A few of the shoots that will break away will carry late blooms, and be useful. The early-budded Briars have the lvs loosened, and all shoots have been rubbed off the stocks. Put in outtings of bedding plants of various kinds; shall continue this work, as outtings can be obtained through the greater part of September, as a large stock is required. Increased oow of Tulted Fansies, with the view of doing more with them next year. Carnations also are being propagated more largely, both from outtings and layers, and a few of the plants are discarded. Pricked off more perennials of various kinds. Potted up Double Wallflowers from seed-bed, or rather from the bed where the seedlings were pricked out; shall winter lo pool-house, near the glass. When well grown Double Wallflowers are splendid things in pots under glass. Brompoo Stocks are also worth attention. Put in outtings of the leading shoots of Chrysanthemum for blooming in 5-inch and 6-inch pots. Tied Dahlias. A good deal of attention is required oow, if not secured, will be a gale of wind would do much harm, and their effectiveness would be gone. Gathered seeds of several new kinds of Sweet Peas; whites and scarlets we found the most useful for outting. Gathered early Beans and Apples. Of course, the earliest Pears, the Jargonelles, &c., are gone. Put in outtings of a collection of Pentstemons, also a dwarf Yellow and White Actinidium, which is found very useful for massing. They are far more reliable than Cestodias, and by picking the seeds of they continue flowering all the season. The outtings are wintered in a cold pit, the pots plunged in ashes. Pentstemons are kept in the same way. Potted off Hollyhock outtings, which are now well rooted. Thinned the foliage of Tomatoes outside. There are still a good many fruit to ripen. These will be gathered before frost comes, and ripened indoors. Uddes glass the crop has been heavy, and the plants clean and healthy. I noticed that when Tomatoes under glass are sown in the fault of the ventilation, chiefly through cooling sufficient air. Shifted out Chierarias, Primulars, and Cyclotenus. A large stock of Primula obconca are grown; the flowers are loud very useful in winter. Potted early bulbs for forcing. Roman Hyacinths are in considerable demand between November and Christmas. The Early-flowering Narcissus and Lilium candidum have also been potted in quantity. I always think both Narcissus and Lilies should be potted sooner than they commonly are. Very busy among the Chrysanthemum, tlyng and thinning beds. Top-dressing of pots soil has been given to all the autumn-flowering varieties, and liquid-manure as required, generally about two or three times a week; but in the employment of stimulants judgment is required, so weakly habitued plants will be better without when the buds are getting prominent.

4373.—Destroying Nettles.—Perseverance is necessary in your case. It is rather awkward to get at the Nettles and, at the same time, not injure the shrubs. Keep on cutting them down, they will not stand this for long. The roots should be forked out if possible, but care must be taken not to injure the roots of the shrubs. See that seedlings or hits of the roots springing up are thoroughly eradicated. In time with perseverance you will get rid of the Nettles.—C. T.

It is quite easy to get rid of Nettles. The best plan is to persistently cut them down with a hoe. As soon as they appear above ground in the spring cut them over just under the surface of the ground with a hoe. They will, of course, sprout again; but before much growth has been made at them with the hoe again, and if this is done as soon as they begin to grow each time the Nettles will disappear entirely by the end of the season. If a few weak growths should appear next year cut them over as in the previous year.—J. D. E.

4370.—Frogs.—The small green tree-frog does not become a tadpole, but is hatched from the egg as a perfect frog. The spawn should be kept with damp leaves or Grass; when the little frogs are hatched they will feed on small insects, as the adults do. If "C. B. S." can spare a small quantity of the spawn, and will kindly send it by post in a bottle with some damp Grass, it would be most gratefully received by—P. ASHETON, Birmam, Cambridge.

* In cold or northern districts the operation is referred to under Garden Work in the above mentioned place a fortnight later than is here indicated with equally good results.

INDOOR PLANTS.

TUBEROUS BECONIAS AS BASKET-PLANTS.

A very beautiful basket-plant is the Tuberous Begonia when such varieties as pendula, which has naturally a pendent habit of growth, are selected. Too little use is made of this flower for filling baskets in stove and greenhouse, and all thought seems centred on it as a garden flower. But we have seen many charming baskets filled with this variety, and they are a decided relief from the majority of things used for the adornment of the plant house. We have on many occasions referred to their cultivation, and it is, therefore, unnecessary to do so on the present occasion, but we may remark that the Tuberous Begonia is especially well adapted for those who have small houses, as they are inexpensive, easily grown, and look bright over a long season. Many things associate well with them, such as Ferns,

with vigorous side-shoots can be had if space is given them always to prevent their being drawn up weakly, but the plants even then cannot be kept dwarf. *E. citriodora* is very similar in leaf and growth to *E. globulus*, except that it does not run up so high, and has not that exquisite glaucous tint in the leaf so clearly defined as in the case of *E. globulus*. Cuttings of any variety of the Eucalyptus family do not strike readily. Even when the plants are cut down close to the soil, the shoots resulting quickly assume their natural tendency.—S. P.

TABERNÆMONTANAS.

This is an interesting genus to which my attention has been drawn by "J. Cromer," who lately sent me a spray of a plant with rich yellow flowers, but they quickly fall, so that if they are to be kept upon the truss a wire should be attached to them. This kind is *T. grandiflora*. Now there are several of these plants which well deserve attention from the amateurs having small stoves in which to accommo-

donble, of medium size, and pure white. They are very useful for personal decoration, as they go well with Maiden-hair Fern, and better than Gardenias for this purpose, because they do not emit such a fulsome perfume. It does not require much pruning at any time.

T. CAMASSY is a plant with large flowers, and much larger leaves than the preceding. Its flowers are double and pure white. It is useful for bouquet making, or to adorn the hair.

T. GRANDIFLORA forms a neat compact shrub, and I would recommend it to decorate the stove in preference to any other purpose. The flowers are very freely produced. They are single, and a rich deep yellow in colour. J. JARVIS.

4323.—*Musa* from seed.—The best way to get *Musa Cavendishi* is from suckers, carefully taken off before growth becomes too advanced, and potted in pots that will only just hold them, then repotted from time to time until they bloom and fruit. *M. Cavendishi* bears at the height of about 6 feet, while some of the other kinds do not flower under 12 feet or 15 feet. The soil they grow best in consists of two-thirds rich loam from rotted turves, and one-third of well-rotted manure. They require a warm corner of the stove.—H. B. I.

4387.—Heating frames.—To maintain a temperature of 60 degs. through the winter in all weathers you will want a considerable length of piping, and a 4-inch will occupy too much of the space, you had better use 3-inch. Two rows of this size (both flows) along the front, and a single pipe as a return along the back, will give you all the warmth required. For such a purpose I should use a dome-shaped cast-iron boiler, which requires no brick work in setting. No doubt your frames are facing south. If so, have the boiler fixed at the east end, near to the front corner.—J. C. C.

Use a 2-inch flow along the front of the frames, and a 4-inch return—or two 2-inch pipes will come to just the same thing—along the back. I expect you will want some bottom-heat as well in part of the frames at least. If so, put in three 4-inch pipes—two flows and a return—in a small chamber, with corrugated iron and Cocoa-nut-fibre over. Supposing there is equal to 100 feet of 4-inch piping altogether, an independent upright "Star" or "Gem" boiler will heat it steadily and well.—B. C. R.

4361.—*Pot Mignonette*.—I think one of the secrets of market growers' success is the firm way in which the soil is rammed into the pots. Good heavy loam slightly enriched with old manure rammed firmly into the pots, the seeds sown thinly, and the weakest plants afterwards drawn out, leaving about four in a 6-inch pot, will yield good results.—E. H.

4360.—*Myrsiphyllum asparagoides*.—This is an evergreen climbing greenhouse plant. It is easily raised from seed, and in appearance not unlike the ordinary Chickweed of the garden. It is much used for personal adornment. If "B. C. S." wishes to grow it for that purpose some vertical wires should be provided for the growth to climb to, or the numerous shoots that spring up from the crown get so entangled that it is a difficult matter to separate them.—J. C. C.

4369.—*Stephanotis floribunda*.—There is nothing unusual in this plant showing fruit. Many instances are yearly recorded. The fruit is not edible, and only useful for the value of the seed for raising a stock of young plants, not that they are any better than those raised from cuttings. It is perhaps easier to grow plants from seed than cuttings, but they are not any better for flowering purposes. If the plant is not strong and the seed not required, I should remove the seed-pod, as it will only weaken the plant in consequence of the strain upon its resources.—S. P.

—The fruiting of this plant is not a rare occurrence. The fruit is not edible. Have nothing to do with it in this way.—E. H.

—I have seen this plant bearing fruit occasionally, but the occurrence, caused no doubt by the intense heat and drought, is not at all common. I have never heard that the fruit is edible, and should recommend its being allowed to ripen and produce seed.—B. C. H.

Drawings for "Gardening"—Readers will kindly remember that we are glad to get specimens of beautiful or rare flowers and good fruits and vegetables for the purpose of illustrating our articles. The drawings should be engraved in the best manner, and will appear in due course in the next issue.

Tuberous Begonia as a basket plant.

Isoplepis, Ivy-leaved *Pelargonium*, variegated *Eulalia*, and other well known subjects. All may be cultivated with success by amateurs, and for window-boxes also they are well adapted. The illustration shows well the beauty of the Tuberous Begonia as a basket-plant, and displays a certain gracefulness of habit not seen in those in the open.

4391.—*Eucalyptus globulus*.—The natural tendency of this Gum-tree is an upward one, therefore it is most difficult to keep them dwarf and bushy; even when the point of the leader is pinched out when the plants are but a few inches high, they quickly make other growths upwards. It is so very easy to grow that it seems to be a waste of time and space to keep them over the winter, except plants 6 feet or 8 feet high are required for hedging purposes or otherwise. Plants 5 feet high can be obtained by the month of August if seed is sown early in February in a gentle heat, afterwards hardening them off and keeping the plants close to the glass to prevent their being drawn up weakly. Those

date them. They are very easy to grow, and yield a profusion of flowers. They succeed well potted in a mixture of loam and sandy peat. The pots must be drained well, and I have found, too, that *Tabernæmontanas* like rather small pots; in fact, they give a large crop of flowers when the plant becomes somewhat pot-bound. They should have a slight pruning every year to keep them in order. In general appearance they resemble the Gardenias, and may be treated in a similar manner. The following kinds are all well deserving the attention of everyone having a stove-house, and I should be glad to see many of these good old kinds become popular again.

T. BARTERI is strong-growing, with large leaves, and from the forks of the branches it produces bunches of large funnel-shaped flowers, which are five-lobed and pure white. This plant requires to be cut back every season a little in order to prevent the specimen becoming thin and scraggy. This makes more young wood, which produces flowers.

C. PURONARIA, PL. 12 is of compact growth, and an abundant bloomer. The flowers are

UNIVERSITY OF CHAMPAIGN

ORCHIDS.

EPIDENDRUM ATROPURPUREUM AND ITS VARIETIES.

This is a plant with a wide range in South America, and that may account for the variation in colour of some of the flowers sent me by "Andrew Cochrane," which he tells me came from Caraccas; but I am sorry to find you have not got the pure white form. All are more or less highly coloured. The variety popularly known in English gardens as macrochilum roseum has the flowers smaller than the normal form, and there are several others. It would appear to have been first found by Humboldt, and it was named by Willdenow *E. atropurpureum*, and the name was published as macrochilum; but although this name has become the more popular amongst gardeners, it cannot supersede the one first published. One or two inferior kinds occur in this large genus, which are unintentional mimics in growth. When you may be thinking you are picking out a nice plant of the species called atropurpureum, you get a variety having a very dull, small-flowered kind. To grow these plants aright, they must be cultivated so that their roots can ramble free in the air. I generally like to use blocks of wood for them, using good-sized blocks, and binding them on with copper wire, placing some Sphagnum Moss about their stems and roots. Keep the atmosphere moist during the growing season, for they are very fond of moisture during growth, but after this has ceased much less will be required. Do not over-dry them; indeed, I have seen more injury arise from this being done too severely than any cause. Some require a very warm temperature, others will only grow in the coolest and most moist place, but the kind we have now under consideration thrives best during the growing season in the Cattleya-house or an ordinary stove. During the resting season it may be removed to the cool-house. These remarks apply to the plant here mentioned, many of the kinds making a tall reed-like stem, requiring attention in the way of watering at all times of the year.

E. ATROPURPUREUM is the plant frequently called in gardens *E. macrochilum album*. It has ovoid bulbs, some 3 inches high, bearing usually two leaves, which are leathery in texture, of a dull, greenish hue, and about a foot in length. The flower-spike springs from the top of the bulb from between the leaves, and grows erect to about 18 inches or 2 feet, bearing about seven or eight flowers or more. Each is upwards of 2 inches across; the sepals and petals are similar in size and shape, incurved somewhat, leathery in texture, and of a dull brown, bordered with a greenish-yellow. The large lip is pure white, being rosy-purple near the base. The flowers are stout in texture, so that they remain in full beauty for several weeks.

E. ATROPURPUREUM ROSEUM is frequently to be met with under the name of *E. macrochilum roseum*, and it is the plant of which my friend "A. C." sends me several flowers, the one marked 3 being about the best. This is known as the Boas del Dragon, or Dragon's-mouth, by the residents in Guatemala. It is for the most part rather smaller in size than the above-named typical kind. The sepals and petals are of the same colour, but the lip is of a rosy-purple, having a deep-rose coloured blotch at its base.

E. ATROPURPUREUM RANDIANUM is a somewhat newer kind, that has been found in a new neighbourhood, that is at a place called Tefé, on the banks of the River Amazon, and other spots. It differs from other varieties in having flowers slightly superior in size to even those of the typical plant; but they are of the same stout texture. The sepals and petals are broader and of a greenish-brown, margined with light yellow, the large lip being white, with a deep-rosy purple blotch at the base. All these plants are superb ornaments to the stove or the Orchid-house, and last a long time in full beauty.

MATT. BRAMBLE.

ORCHIDS IN A VINERY.

HAVING a vinery about 20 feet long and 12 feet broad, but unheated, I determined to put a "Siphon" gas-stove in it, and try and grow a few Orchids. I owe a debt of gratitude to the gentleman who writes under the title of

"Matt. Bramble," for all that I know about Orchids comes from reading his advice on the subject. My plants have cost me on an average two shillings each. At first, of course, they are small, but in a very few years they increase greatly, not only in size, but in value. All the care they get is to be watered once in ten days or so in the summer, and less frequently in the winter, and in the spring, summer, and autumn I wash their leaves with a soft sponge once in two months. The windows of the house, top and sides, are opened every day, except in frosty weather, at eight, nine, ten, or eleven a.m., according to the time of year, and closed again at three, four, or five p.m.

THE FLOOR of the vinery is kept constantly damp, even in the most severe frost. In December, 1892, and in January, 1893, the evaporation from the damp floor gathered on the inside of the glass roof, and there froze into a solid sheet of ice every night for several weeks, not melting each morning until ten a.m., and sometimes not until eleven a.m., yet the Orchids did not seem any the worse, and in due course have flowered this year very finely. One of them, *Coclogyne cristata maxima*, had ninety-six large blooms open at once in March, and remained four weeks in full beauty. I enclose you a list of the Orchids which I have in this cold house, and which have no shading at all, except what they get from the leaves of the Vines. Fifty or sixty pounds of ripe Orapes is a very pleasant adjunct to the beauty of the Orchid flowers; besides this I find that *Tuberous Begonias* and *Olexiass* thrive very well in this house. I never water overhead, but place the pots in a pail of tepid water until well soaked. It seems to me that a very great deal of pleasure can be derived from a very small outlay, and with very little trouble or expense after the first outlay. I am not sending you this account in a spirit of boasting, but in the hope that some who fall in with, but yet fear to try, may be encouraged by my experience. The following is the list of Orchids in bud or in bloom during the excessively cold weather of December, 1892, and January, 1893: *Odontoglossum Rosae majus* (lasted fifteen weeks), *O. Edwardi* (lasted four weeks), *O. Cervantesi* in bud, *Cypripedium insigne* in bud, *C. Maulai* (lasted five weeks), *Coclogyne cristata* in bud. This is a full list of Orchids in vinery in addition to the above: *Cypripedium barbatum nigrum*, *O. Schlimi*, *C. grandiflora superbiens*, *O. macranthum*, *C. apotabile*, *C. calceolus*, *O. venustum*, *O. Sedeni*, *Calanthe Veltchii*, *O. veratifolia*, *Cattleya citrina*, *O. Mossii*, *O. Mendeli*, *Coclogyne cristata maxima*, *C. speciosa*, *Cymbidium eburneum*, *C. Lowianum*, *Dendrobium nobile*, *D. thyrsiflorum*, *D. chrysotaxum*, *Lelia anceps alba*, *Phaius grandiflorus*, *Lycaste Skinneri*, *Coeliodora vivescens*, *Odontoglossum Alexandri*, *O. Rosae majus*, *O. maculatum*, *O. pulchellum*, *O. pulchellum majus*, *O. grande*, *O. citreum*, *O. triumphans*, *O. Uro-Skinneri*, *Dendrobium densiflorum*, *Sophranitis grandiflora*, *S. violacea*, *Oncidium flexuosum*, *O. sphaerolatum*, *Trichopilia suavis*, *Psecocheia olivina*.

ORCHID LOVER.

4378.—**Neapolitan Violets.**—You may obtain a few flowers from the plants in the spring if they are carefully taken up towards the end of September with a good ball of soil attached to the roots and planted in a cold frame in gritty soil, keeping the plants close up to the glass. No artificial heat is necessary during the winter, simply protecting the foliage from frost by covering the glass with mats and the sides of the frame with long manure or leaves, so that the roots are not frozen. Violets during winter do not require much moisture at the roots, just enough to maintain the soil moist, but they enjoy abundance of air. Directly the thermometer out-of-doors stands above 35 degs., pull the lights entirely off the Violets. A molching of decayed leaves an inch or so thick laid on the soil between the rows will assist the growth for the next month. The soil should not be allowed to become dry, so as to check the growth of the new leaves that are now appearing above the soil; but these should be encouraged to grow freely, so as to make up somewhat for the time lost in allowing the plants to suffer so severely during the recent drought.—S. P.

Put them in the frame, but not yet. Let them grow, and, if possible, get the buds opened, and plant in frame in September, towards the end of the month. It was a pity the plants had not been dipped with mulch and water during the drought.—E. H. KIRK

FRUIT.

4385.—**Vines in pots.**—The pots are too small, and probably the canes are in the same condition to fruit satisfactorily. As it is too late now to do any good by shifting them into larger pots, you had better let them remain as they are until the winter. Early in December cut them down to two eyes, and a month later shift them into pots 14 inches or 16 inches in diameter. If they are grown on in these pots next year, and the canes trained near the glass, they will give a crop of fruit the next season.—J. C. C.

—The young Vines should be repotted into 10-inch flower-pots, using good retentive loam, well enriched with decayed stable-manure and half-inch bones. Pot firmly, and if the Vines are well managed good fruiting canes can be produced from eyes put in about the end of January or early in February. I have had such Vines strong enough to well fill 11-inch and 12-inch flower-pots with roots. Seven-inch pots are not large enough to fruit Vines in. I have seen a few nice bunches obtained from 9-inch pots.—J. D. E.

—Seven-inch pots are too small for fruiting Vines, if the Vines are very strong. Shift at once into 10-inch pots. It not likely to make fruiting-canes this year the 7-inch pots might do for this season, the Vines in be out down in winter, and a fruiting-rod to be grown next year.—E. H.

4372.—**Melons.**—I am afraid you commenced too late in the season to prove successful with Melons. Amateurs should get their plants set out on a warm hot-bed by the middle of May. It is too late now for them to do any good this season. From the information you send I think you have given them too much water, and allowed the growth to get overcrowded. Another year do not stop the shoot on which there is any fruit forming, but lift it well up to the light, so that the sun and air may assist in fertilising the flower.—J. C. O.

—The young Melons were not, in garden phraseology, set, or the fertilisation had been imperfect, and the fruit failed to swell. This might arise from more than one cause, the most likely one being planting in soil which is too light and too rich, which has produced great growth. Melons do best in rather heavy loam, made firm.—E. H.

4364.—**Strawberry border.**—Now is a good time to set about the preparation of the land for a Strawberry plantation. It is a mistake to defer the planting until the winter or even during the spring. Plants put out before the end of September will produce a fair crop of fruit next season; but those planted later will not do more than become established in the ground for another year. Commence by trenching the soil 18 inches deep, keeping the top spit still on the surface. The ground should be liberally manured; nothing is better than half-decayed farmyard manure. This should not be buried too deeply, or its goodness will be lost before the roots reach its vicinity. Choose showery weather for planting, and carefully lift the runners from the soil where they were rooted, planting them carefully with a trowel so that the roots are not cramped, but spread carefully out in all directions. The rows should not be less than 2 feet apart, and the plants 18 inches in the rows. The kind of soil and the manner of growth is, however, important; in some localities the plants make so much more foliage than in others that more space is necessary. Keep the plants free from weeds, and the soil regularly stirred between the rows. Except for the purposes of forming a collection, a great number of varieties is neither advisable nor necessary. Viscomtesse Hériotte de Thury is about the best of early sorts. Sir J. Paxton as a main-crop variety and Waterloo as a late bearer are about all that are necessary to give a full supply of fruit the whole season.—S. P.

4385.—**Vines in a cool house.**—I suspect the cause of the leaves becoming yellow is owing to the roots becoming too dry, or it may have been the work of the red-spider, although there is a difference between the changing to yellow from drought and to a rusty brown from the work of this insidious pest. Either cause will bring about the damage to the leaves—in any case, the loss of foliage is injurious to the Vines. Thoroughly soak the border, whether it is an inside one or not, with clear water, wetting every particle of soil where there is a root. In the evening, after a hot day, thoroughly syringe the foliage with clear water, using some force to

the underside of the leaves. If the foliage exhibits an improvement in colour cease syringing for a few nights. When the Orapes are cut well syringe the Vines with Tobacco-water, soft-soap, and a small quantity of sulphur added, choosing the evening for the operation, thoroughly washing the leaves the next morning with clear water. Repeat this dose several times, even if the leaves should appear to be cleaned from the insect.—S. P.

CORDON-TRAINED FRUIT-TREES.

ALTHOUGH the cordon form of training fruit-trees may not excel other modes of training, there are circumstances connected with it which render it peculiarly well adapted for certain

Rednettle du Canada Apple.

purposes, particularly Pears on walls. In this case its advantages are manifest; the trees not only come into bearing quicker than when fan-trained, but one is able to grow a tolerably large collection of varieties in a limited space—a particularly valuable feature belonging to this mode of training, for in but few places is a large hulk of any particular variety required. Five or six dozen fruits of such large sorts as Doyenné du Comice will suffice for the majority of people. The old adage, "Those who plant Pears, plant for their heirs," is no longer applicable to this improved form of fruit culture. In saying this, I do not mean that cordon-trained trees are more certain bearers than any others, because they are not. Our climate is such that no form of trained tree escapes its influence. Therefore, as regards securing regular crops, one form of training is about as good as another; but the fact that the trees come into bearing the third and fourth year after planting, and that the cordon plan admits of a wider choice of sorts, is sufficient to stamp its merits. Even away from walls cordon-trained trees are much better than pyramids, and why they should be so is not difficult to explain. One word, in fact, clears the matter up—viz., shelter. I maintain that a cordon-trained tree whose branches are not more than 18 inches from the ground gets a great deal more shelter from surrounding walls and other objects than a pyramid from 6 feet to 10 feet high; and this difference as regards shelter is sufficient to explain, as I have said, why cordon Pear-trees bear more regularly than pyramids, and the same remark is equally applicable to Apple-trees trained in the same way. In the matter of stocks for Pears, the character of the soil must influence the decision. In a strong soil, fairly retentive of moisture, the Quince is no doubt the best stock, as it promotes early fruit-bearing; but in other kinds of soils the Pear-stock is more reliable where a judicious system of root-pruning or lifting is practised. Many prefer the Quince as a stock where the soil soaks it, and when they have come to understand how to treat it in particular cases, on account of its reducing the vigour of the branches; but we have proved in our own practice that, when judiciously handled, the Pear-stock can be made to produce a fruitful tree nearly as soon as the Quince. The direction in which the branches are to be trained is a point on which there is some difference of opinion, some preferring the oblique, and others vertical training. The oblique form has, however, a better appearance than the vertical when the trees are trained against walls.

In regard to pruning this form of tree, I do not agree with persistent pruning. I am satisfied that that system does not increase fruitfulness. In my own practice I go over the trees twice during the summer with pruning nippers. Early in July the leading shoots are nipped in, and all the others are shortened back, so as to leave about 1 foot in length of the young wood. In the case of vigorous trees they soon rush into growth again, and send out two or three young shoots from the points of the young wood that was headed back. By doing this we preserve the buds close home, so to speak, intact, and at the same time make the appearance of the trees presentable. About the end of August I go over them. This time I cut the shoots that before were topped back to a spur. If after this there is any disposition in the tree to form any flower-buds on the spur, there is time enough for it to do so; but I do not prune with the idea that I can always place a fruit-bud where it is wanted. If a tree is managed in a rational manner, that is to say, if the roots are fairly well nourished, and any excess of vigour checked by judicious root-pruning, it will always produce more fruit buds than it can mature fruit. With respect to the management of the roots of cordon trees, if they are Pear-trees on the Quince and form a single cordon, we may be sure that the soil will soon get full of roots, and that what goodness it contains will soon be exhausted. It will, therefore, be necessary to keep up fertility by rich dressings of rotten manure spread on the surface. This is best laid on now, so that the rain may wash what nutriment it contains down to the roots, and unless the soil is naturally holding in its character, trees growing on the Quince-stock will want assistance in dry weather in the way of watering. Now espalier and cordon Apples and Pear-trees should be planted near the edges of walks. Plant them the same as other trees, and they will require some stakes or other supports to train the branches on. This type of tree produces very fine fruit, and is especially useful for small gardens. The first season it is necessary to keep the trees quite free from insect pests, and on no account overcrowd the growth. Pinch off the growth with, if possible, the finger and thumb, which is better than a knife. Stopping promotes fruit-buds at the base of the spurs. There is then less need for pruning in winter. Four very good Apples for growing as cordons or espaliers are White Calville and Reinette du Canada, two very good cooking varieties; and for the dessert, Cox's Orange and Ribston Pippins. J.

4834—Early Strawberries.—The use of glass frames will, of course, hasten the ripening of the fruit if you attend to the ventilation and give the roots of the plants sufficient water. Noble is the earliest of all the large-fruited kinds; but if you prefer flavour to size you had better select King of the Earlies. With regard to planting, if you can get early runners that were laid in pots they would give you a few fruits next year if planted at once. I observe, however, that you do not take possession of the garden until Michaelmas, so you had better defer planting until next spring. Before planting mark out the space your frames will cover, and set out the plants so that the frames will cover a certain number without injuring any.—J. C. C.

4394.—Mealy bug on Vines.—This insect is about the worst that Grape-growers have to contend with. It is possible to cleanse the Vines, but much persistence is absolutely necessary to acquire the end in view. The hunches may be cleaned by thoroughly washing them with clear water, applied with force through the syringe in the evening. It can be more effectively done after the Orapes are cut, however, if one person holds the bunch firmly in a downward direction, and the second forces the water amongst the berries, the mealy-bug will be forced out of its lurking. If the syringing is done two hours before the Grapes are required for use, the berries will dry in that time, if the hunches are hung up where the air can pass through them. After the Grapes are all out the Vines should be thoroughly washed with Tobacco-water and soft-soap. One pound of Tobacco paper, thoroughly well soaked in hot water, to 1½ lb. soft-soap, will suffice for twenty

gallons of warm water. Repeat this dose in a week's time, and thoroughly wash the Vines every night with clear water also. When the leaves have fallen, and the Vines pruned, remove any loose pieces of bark that would provide a hiding-place for the mealy-bug. Thoroughly scrub the canes with hot-water and soft-soap at least three times during the dormant period of Vines. When new growth commences to push the following spring, some few hunches are sure to make their appearance. At once these should be killed. Nothing is better for the purpose than Fir-tree-oil, diluted with water at the rate of one part to three, just touching the insects with a small brush. Inconstant attention throughout the whole of the growing season will reward the cultivator with clean Orapes, if the Vines have not absolutely cleaned themselves, and without the risk of employing insecticides that are dangerous in inexperienced hands.—S. P.

4389.—Old Vines.—Your suggestion of replanting the vineyard with new canes in a properly prepared border is undoubtedly the correct one in preference to attempting to renovate the old Vines. If a new border has to be made for these it is far better to make it for the young canes, because these latter will exceed so much better than the old Vines put into a new border. Whether you plant new Vines or renovate the old ones do not make the border too deep—2 feet 6 inches of soil, with 9 inches of drainage is ample. Arrange the base of the border in such a manner that surplus water runs to one side to be carried away by a properly-laid drain, thus preventing stagnation of the roots by too much moisture laying about them. Over the drainage lay a single, freshly-cut turf to prevent the fine soil running down among the drainage, and thus choking the passage-way for water. Do not add fermyerd-manure to the soil; but half-inch bones at the rate of ½ cwt. to every load of compost. If the soil be heavy add charcoal and old lime rubble freely. If freshly-cut turf is employed for the border do not cut it up too small, pieces 4 inches square being fine enough. The border should be made when the ingredients are in a fairly dry state, so that it can be trodden down firmly, which could not be done if the soil was wet, for fear of its caking together. Any time during the autumn or winter is a suitable period for making a new Vine border. The month of February or March is a good time to plant new canes. If the border is an outside one it should be covered to prevent it becoming too wet before the roots are running into it, thus causing the soil to be an inert mass. If the old Vines are retained cut several of the rods off close to the junction from where they spring, and thus encourage other shoots to push into growth and make stout canes.—S. P.

— It will pay better to take the old Vines out and plant young ones, doing the work at once. Still, we know old Vines have a good deal of recuperative power, and if

White Calville Apple.

the roots are carefully lifted, and a good border made for them, there is no reason why they may not recover. The Vine is a long-lived plant, and under good management all things are possible.—E. H.

4390.—Treatment of fruit-trees.—When young-trees are planted in even moderately rich soil they invariably make a quantity of gross growth. The strongest shoots should be cut out entirely at once, provided there are

(others near to them) will retain the shape of the tree; and if these latter are comparatively weak, as compared to those so strong they will be preferable to the stronger ones. Train all the shoots as thin as space will admit—quite 4 inches should be allowed between them; where the growth is strong 6 inches is not too much from one shoot to its neighbour. When they are retained cut numerous the leaves of one shoot overlaps those of its neighbour, thus preventing perfect maturation of the wood; without this latter it is useless to expect a full crop of fruit. Any lateral growths upon the current year's shoots should be cut off at once, thus giving more space to the main shoot. It will be well to root-prune the trees the first week in October. Cut a trench 3 feet from the stem as deep as roots are found, covering all cleanly at the side of the trench nearest to the tree, paring the end of each with a sharp knife to induce them to make fibrous roots. With this check, and the shoots trained thinly, a full crop of fruit may be expected next year.—S. P.

4366.—Grapes splitting.—Defective treatment is the cause of the berries of all Grapes splitting. Some varieties, though, are more subject to this than others, notably Malheur Court, which is a thin-skinned variety. In the case of Gros Colman I should say the soil has been allowed to get too dry several times, thus giving a direct check to the swelling of the fruit. Are the berries affected by rust, which is distinguished by a rusty appearance of the skin, which injures the tissues, preventing the berries expanding properly, and causing them to crack in consequence? Are you sure the variety is Gros Colman?—S. P.

—Irregular watering will cause Grapes to split. If the vines had been allowed to get dry at the root, and then heavily watered with stimulants, the skin would split from the sudden pressure.—E. H.

THE KITCHEN GARDEN.

AUTUMN-SOWN ONIONS.

WHEN well cared for, autumn-sown Onions are a very useful crop, as they commence to come in, or at least are large enough for use during the spring if varieties suitable for the purpose are selected. They also form the main crop for summer use, and are valuable far into the autumn when well ripened and stored. By the spring months the main crop of stored Onions will be over, and if preparation is not made now, or at least from now until the end of the month, or according to the district, Onions will be lacking when they are really required for daily use. Indeed, where the main spring sowing partially fails through unforeseen circumstances, such as from the depredations of the Onion-maggot, mildew, or, indeed, very late ripening, it is essential that autumn-sown Onions should not be overlooked as a means of keeping up the supply. Occasionally one hears of failures through frost during the late winter or early spring months, but such losses rarely occur. I think the failure of autumn-raised Onions may fairly be attributed to too early sowing, coupled with a loose soil, those being just the conditions to favour a stronger and earlier growth than is necessary for their successfully combating severe or prolonged frosts when these should happen to be of undue severity. What is needed for their successful growth is a well-drained soil.

THE soil should also be in a fertile and well-pulverised condition. It is rarely that the maggot attacks Onions which are sown at this date, so there need be little fear of injury from this cause. It will be noticed that a rather gritty soil makes the best seed bed, and on stiff clay land it will be found very advantageous to add some other matter to assist in getting the soil into this condition. Coarse sand, burned refuse, and such like material are the best and more likely to favour a successful growth. Another source of failure with these autumn raised Onions in private gardens is on account of the seed bed not being in a sufficiently exposed position. Very often it is in close proximity to trees, and as the leaves from these fall they blow amongst the Onions and smother them up. Autumn-raised Onions follow well on land recently cleared of early Potatoes or Cauliflowers, and the soil has been well prepared for these or peas, or after manuring, very little assistance will be needed

in this respect. It must not be inferred, however, that poor soil will give equally good results, and if there should be the least idea of the soil wanting in fertility, then ought the site to receive a dressing of well-rotted manure. In either case, whether the soil requires manuring or not, a dressing of sifted burned refuse and soot should be applied direct to the surface previous to levelling down and drawing out the drills. The soil must be equally trodden over so as to form a firm surface, this being preferable to rolling.

THE SEEDS if sown thinly will germinate evenly, and the seedlings will not require thinning in the least until fresh growth starts in the spring. Surface-hoeing must take place directly the young Onions are visible, this keeping down weeds. When kept clear the air circulates freely among them, and a slight surface stirring will impart a healthy growth, and such as will withstand frost. Different districts have certain times for sowing, and what would be early in one district would be quite late enough for another, and vice versa. In the northern districts the first week in August is none too early, and in the south from the middle to the third week. In either case this will give time for the seedlings to appear well above the soil before the wet days of autumn are upon us. Those of the

TROPICAL section are generally selected for autumn sowing, a good selection of Giant Rocca being perhaps the best for general use. It is mild in flavour, grows to a large size, and is also a tolerably good keeper when harvested well. This is most important when the bulbs require to be kept as long as possible; consequently it will depend upon how this part is carried out whether they will decay quickly or not. The Early White Naples and large Italian are also good kinds of the same section; the former, besides growing up to a useful size quickly, is also a good kind for drawing young during the winter. The White Spanish and also Dauver's Yellow may also be sown now, although it is seldom these are selected for the purpose. This reference would not be complete without a note being made of that excellent little Onion the Queen. It must not be classed with the former, but is most useful in case of emergency if the ordinary kinds are likely to be short the following spring. Instead of sowing in the open with the large kinds, select a sunny border where the soil is fairly light, rich, and also tolerably firm. Shallow drills should be drawn 7 inches or 8 inches apart and the seeds sown thinly. The young plants will grow quickly and be found valuable early in the spring. A.

TOMATOES OUT-OF-DOORS.

THEY has been an exceptionally favourable season for Tomatoes, as they enjoy plenty of heat and bright sunshine, provided the requisite moisture at the root is supplied. One of the greatest drawbacks to the successful outdoor culture of this popular fruit is the shortness of our summers, as it is rarely safe to plant out even against walls until the month of May is half gone. This year one might have safely put their plants out early in April, as we had no frost of sufficient intensity to hurt plants that had been well hardened off by exposure, and where they were got out early, and a liberal supply of moisture given during the intense drought that prevailed up to June, there are now fine crops in various stages of ripening. Should the weather continue favourable, we may reasonably hope for even late crops to ripen well, as I have picked ripe fruit from self-sown plants that are carrying fine crops. Thus far Tomatoes, like Potatoes, show no traces of disease, the weather having been so fine that it looks as if our climate had for the time settled down to something like they get in the fruit-growing regions of California, where the great secret of success is irrigation. If we are likely to get seasons anything like the present, it will be a remunerative thing to go in much more largely for a sufficient supply of water, so that crops may be copiously supplied. J. G. H.

4374.—Manure.—If peat-litter manure obtained from the stables, it may be freely used in any part of the kitchen garden. It has been used for over ten years, and has no hesita-

tion in saying that its fertilising properties are greater than that of stable-manure where straw has been used for bedding the horses. The reason of this, I believe, is owing to the spongy nature of the peat, which absorbs the water, retaining the fertilising properties contained in it.—J. D. E.

4395.—Tomatoes.—The treatment appears right, except that too much syringing is done; some of the best growers never syringe at all. The roots are kept moist, and occasionally liquid manure is given, but the soil is not kept in that saturated state thought necessary by some persons. In a house none too well ventilated too much moisture is a sure precursor of Tomato disease. It is a good plan to give the trusses of bloom a gentle tap about the middle of the day to assist in the dispersal of the pollen, and thus ensure a perfect set. Neither the flowers nor the fruit need thinning, except for exhibition purposes; for ordinary use or for market thinning need not be practised. Continue to train up the leader, removing all side shoots as they appear, but do not denude the plants of too much foliage. This is no easy to give the fruit that flavour and substance to entitle them to being reckoned of high-class quality. Upon the first appearance of disease in the leaves, which is a small black speck, lose no time in dusting the parts affected with brown sulphur, and keep the surroundings somewhat dry.—S. P.

—The treatment described is all right so far; the plants, especially those in pots, require a lot of water this tropical weather. They will, of course, do better if trained near the glass than at a distance from it, but as in an unheated house they will not probably do any good after the middle of October, at the latest they should be stopped about the end of this month, and not allowed to make any further growth.—B. C. R.

4382.—Building a Tomato house.—The width of the bed depends upon the number of rows of plants you intend having, or can find room for. For a single row or bed a foot to 18 inches wide will be quite sufficient, for two rows it should be 2½ feet or 3 feet, and for three 4 feet to 5 feet. The depth may be 18 inches or 2 feet, including drainage, but if the subsoil is naturally porous, do not drain it any more. What do you mean by "stopping the leaves at a joint?" If cutting back the leaves themselves is meant, all the lower ones can be shortened to the last pair of (large) leaflets as soon as the plants become strong—say 3 feet high. If the plants do well, they will fruit all the way up without any stopping, but if weakly stop them beyond the fourth or fifth truss.—B. C. R.

4379.—Tomatoes curling up.—It is only the older leaves that curl; it is quite natural for them to do so, and no harm will result. I regard it as a kind of indication that the plants are doing well indeed—that is, of course, if they are healthy in all other respects.—B. C. R.

White African Lily.—The blue-flowered *Agapanthus umbellatus* is familiar to most gardeners, but although the beautiful white-flowered varieties are by no means new, one does not often see them, yet they are quite as easy to grow, and the flowers are truly white, not milky-white. There are three or more distinct forms—namely, *albus*, *albus maximus*, *albus albilorus*, and *caudatus*, but they evolve themselves into practically one for all general purposes, this being *maximus*. This is a variety thoroughly worthy of good attention, and in a large tub has an exceedingly fine aspect. The flowers are produced in very large umbels, and the individual blooms far exceed in size those of the ordinary type, whilst they are of the purest white, excellent for cutting. If only one white-flowered variety is desired, this may be chosen, and as regards cultivation few things are more easily grown either in large pots or tubs, but they have a very quaint, old-world look in tubs, whilst under such conditions they may be placed either in the conservatory or, during the summer months, in the open ground, at which time it is necessary to give plenty of water. In the winter they may be taken under cover, and if no other place is available store them in an out-house. Good loamy soil is the most suitable as starvation treatment, which the common kind often undergoes, will not bring forth the best quality of buds and flower-spikes to perfection.—V. C.

freely. As soon as the young plants were large enough to prick off they were planted in boxes, and I have grown them in flower pots during the present season because I was not sure whether they would flower out-of-doors. They have been out since May, and would have flowered well in the open garden had they been planted out in May. A few of them will not flower, but most of them will do so.—J. D. E.

4319.—Box.—Prepare the site of the intended line of Box by digging, breaking the soil up well, leaving the surface level. Then tread it down firmly, applying the same amount of pressure all along the line. Rake it perfectly smooth and even; stretch the line along from end to end and draw it tight; this will show the low places if there are any. Make up the inequalities of surface by adding fresh soil, and then heat it down with the back of the spade. Rearrange the line in the required position, and out set the trench from 4 inches to 5 inches deep, according to the size of the Box, so as to have a clean, hard surface to lay the Box against. Dress the Box by cutting off the long roots, and trim the tops quite even. Pull the Box into fair-sized pieces, and in planting hold in position with one hand and use the other to place the pieces in the trench, covering the roots with earth as the work proceeds, pressing it in firmly. Leave about 1½ inches of the Box above the ground. Return the soil against the edging with the spade, and tread it down firmly by passing the foot along with the toe against the edging. The gravel, which should have been turned back, will then be replaced. When the other side of the path has been planted in like manner a sprinkling of fresh gravel and the roller will make a neat finish. If Box is planted in dry weather water should be given till the roots begin to start.—E. H.

4328.—Pansy seedlings.—An east border against a house would be a very good situation for Pansies. The seeds of the Pansies should be sown in July, so that they may be ready to plant out in September where they are to flower, or small plants put out now would become stronger and give flowers earlier in the year. They should be planted in deep rich soil, well manured. It would be too late to plant them in spring for early flowering. Borders on the east side of a house are frequently much exposed to winds. A draught is caused by a fence on one side and the wall on the other. The east wind rushes down in the winter and early spring, but if sheltered from this draught they will do very well.—J. D. E.

It does not much matter what position these occupy; but the blooms will come larger and brighter if in a partially-shaded spot. The time of planting is also immaterial; it must depend entirely upon the stage of our seedlings. Pansies invariably bloom in the spring and early summer, and are perfectly hardy.—P. U.

4334.—Carnations, &c.—The difference between Carnations, Pinks, and Dianthus has been fully explained in these columns in previous numbers. The Pink is a garden flower has been produced from a distinct parentage. *Dianthus plumarius* is the reputed parent of the Pheasant Eye or exhibition Pink of the florists; but some sorts have a nearer relationship to *Dianthus deltoides*. The growth of Pinks is more slender than that of Carnations, and if planted together in the borders the Pinks produce their flowers very nearly a month earlier than the Carnations. *Dianthus caryophyllus* is the parent of the Clove Carnation and Pinks, and as they have been cultivated in English gardens for at least three hundred years, they have taken on a great variety of form and colour, and the florists for exhibition purposes have divided them into sections. They place the bizarre Carnation first; the colours are scarlet and maroon on a white ground, or purple and pink on white. The flukes have but one colour on a white ground, and these are scarlet, purple, rose, and pink. The softs are one colour throughout—rose, pink, scarlet, orimson, purple, yellow, white, &c. Pinks are white, with a margin to the petals of various widths and colours; sometimes there is merely a thin, hair-like line of colour, at other times the margin is an eighth of an inch wide. The colours are deep red, rose, red, purple, rose, and scarlet.—J. D. E.

4362.—Herbaceous plants.—This term signifies plants that die down every year. Herbaceous Phloxes, Michaelmas Daisies, and so forth. I have repeatedly given lists of the best things in GARDENING, but here are the names of

a few plants to commence them. Those that bloom in the spring would comprise the Adonis vernalis, Rook Madwort, *Alyssum saxatile* (a beautiful flower, a mass of yellow in the spring months), Anemones of various kinds, A. nemorosus in variety, A. apennina, A. fulgens, A. pulsatilla (the Pasque-flower), A. sylvestris, the various forms of Candytuft (*Arabis*), the Thrift (*Armeria vulgaris*, very good for edging); Aubrietias, not forgetting the rosy-flowered A. Leichtlini, Cheiranthus Marshallii (Marshall's Wallflower), the Lily of the Valley (very pretty if not planted too thickly and in a shady spot), *Dielytra spectabilis* (the well known Lyre-flower, very good in a light soil and not too exposed a position), the Cantianella (where it can be well established), the spring Hellebores (beautiful things), forms of *H. atro-rubens*, &c.; Forget-me-nots, the bulbous Dog's-tooth Violets, the Winter Aconites, the violet-scented *Iris reticulata*, Daffodils (in variety), Dwarf Phloxes, Crown Imperials, Primulas, Saxifrages, Soillas, or Squills; particularly varieties of *S. campanulata*, Tulips; not forgetting the orimson-flowered *T. fulgens* and Tufted Peneies. As regards the summer-flowering, get Achilles, the Poarl, Hollyhocks, *Alstroemeria aurea* (if you have a warm, light border), *Chrysanthemum C. latifolium* summer-flowering, *D. Iphigeniæ*, *Oreopsis lanceolata*, Campanulas, Funkias, Scarlet Lychnis, Gladiolus, Perennial Columbine, Sunflowers (particularly *Helianthus multiflorus maximus*), *Herbaceous Lobelias*, *Eryngium planum*, *E. Olive-riamum*, *E. giganteum*, *Lythrum roseum*, Evening Primroses, Herbaceous Phloxes, *Galega officinalis* and white variety, Pyrethiums, Roses, *Sedum Sieboldi*, *Gypsophila paniculata*, Cernations, Pinks, *Diotamnus*, *Senecio pulcher*, Tufted Pansies, Dahlias, and annuals of many kinds.—C. T.

4377.—Clematis attacked by mildew.

—It is difficult to say what is the cause of plants being attacked by mildew; but it is usually very prevalent at this season of the year. Roses in the open garden are usually badly attacked with it in August. They are very bad this year, owing probably to the greater dryness of the soil about their roots. The *Wistaria* growing over the Clematis would have the effect of keeping them dry, and hence they would be more liable to be attacked by mildew. *Wistaria sinensis* itself does not suffer from the attacks of this parasite. The best way to get rid of it would be to dissolve about two ounces of soft-soap in a gallon of hot water; mix with it about a quart of a pound of powdered sulphur (flowers of sulphur), and well syringe the affected parts with it. The sulphur soon sinks to the bottom, but it can be kept in solution by syringing into the water each time of drawing it out.—J. D. E.

4381.—Clematis dying.—It is not easy to tell why the Clematis should go off in the way described. Possibly something is eating them at the root. If dead, lift them, and see if there is anything radically wrong in that quarter. Possibly the soil is very poor. If the plants were put in late this spring and have not been freely watered, but permitted to carry a heavy mass of bloom, that will account for failure.—C. T.

4371.—Christmas Roses.—I should think that you would succeed well with the Christmas Roses, but not so well as in the country. The Hellebores require moisture and shade. You may plant now in a deep vegetable soil. Get good clumps, and let them develop into bread, spreading masses. If you require flowers to cut, you must when the buds appear place over each clump a hand-light, which will afford the needful protection from fog, wet, and frost. I once had a small plot of Christmas Roses near London which did exceedingly well. The soil was fairly rich, and the plants in a half shady, moist position. Each year they gave a fine lot of flowers. *Alfifolius* is the earliest in bloom, but at Christmas *St. Brigid* and *maximus* are the best. The flowers are very pure. You need not grow the plants all the year round in pots. The best way in dealing with those for the conservatory is to lift good clumps from the open when in bud, and transfer them to large pots, or better still baskets filled with Cocoa-nut fibre. Keep them in the warmest end of the greenhouse, and you will be rewarded by a fine display of bloom. The next year select other clumps, as they will not bear this forcing treatment two seasons in succession.—C. T.

TREES & SHRUBS.

BEAUTIFUL FLOWERING SHRUBS.

THE usual occupants of the average garden in the way of shrubs are Privet, Laurustinus, Laurels, and Box, which have a monotonous, depressing effect when used too freely. One would think from their frequency that it was a matter of necessity to use these evergreens or put up with vacant forecourts, but there are many beautiful flowering trees and shrubs quite as easy to grow, and not afraid even of the smoke and dirt of town gardens.

One might take the Barberries as examples of shrubs too little seen, although of extreme beauty, carrying throughout the winter a rich profusion of orimson fruits. The most popular is *B. Darwini*, then we can use the common Barberry, *B. vulgaris*, *B. dulcis*, which bears small yellow flowers, followed by ruddy fruits, and the hybrid *B. stenophylla*, all worthy of a place in the smallest garden. It is not possible, of course, to cram all the good things into a limited area, and of Barberries, our selection would be *B. Darwini* or *B. vulgaris*, obsoleting from the Evergreen Barberries, or Mahonias as they were formerly called, the rich, hrenzy-leaved *B. aquifolium*, the leafage of which is excellent to associate with out flowers, Daffodils and *Chrysanthomum* in particular. All the Barberries will grow freely in ordinary soils, and make a brilliant picture of colour in the winter. Against a wall the *Crataegus pyracantha* or Fiery Thorn is very beautiful, the best variety, because producing a freer display of berries, being the orange-fruited *C. Lelandi*. Its rich-green leafage and brightly-coloured fruits are remarkably beautiful in association, and the milky-white clusters of flowers in the summer months possess much attraction. But this is not the only Thorn that is of value in the garden. The Thorns are, perhaps, the most interesting and charming of garden trees; their picturesque growth, hardiness, vigour, and extreme beauty adapting them for the smallest plot. What exceeds a healthy tree of the double crimson variety, or Paul's Double Scarlet? Whilst the range of varieties may be extended, embracing pinks, carmine, and white, but, as a rule, after the Fiery Thorn, the selection will have to be limited to one, and that the orimson form of our Common "May." Then we have the Cockspur, Washington, and Scarlet-fruited Thorns, all necessary in a large garden, but must be omitted from small places if a variety is desired.

How seldom one sees a Catalpa in gardens, yet it is a splendid tree where there is space for it to spread out and reveal its true character. *C. higuonioides*, or *C. eryngifolia* as it is also called, is the commonest type, its large leaves of great beauty; and then we get in August the Horse-Chestnut-like flowers, charmingly spotted and very attractive to the eye. I know town gardens in which this North American tree thrives to perfection, and it succeeds better if provided with shelter, and the position is moist. The glorious old

JUDAS-TREE has for hundreds of years figured in English gardens. It makes a picturesque growth enriched with purplish-rose flowers. I have seen this old favourite in town gardens, and in the suburban seat of Mr. Leopold de Rothschild, at Gunnersbury, there is a noble example clambering over a wall, for it may be made to embellish a wall, as the *Wistaria*, as well as grown in the form of a low tree. It must be a poor garden and soil that will not grow the quaint, old-fashioned *Cercis*. Brilliant and delightful to look upon when in fruit is the *Cotoneaster*, and on a bank or shrubbery margin the common *C. microphylla* will be quite at home, clothing the bare places with its wiry growths and small leaves, lit up during the winter season with scarlet berries. Sometimes there are stone steps in gardens which it is desired to hide, and the *Cotoneaster* is exactly suited for such a purpose, growing in ordinary soil and positions. It is quite a dwarf, spreading shrub, clothing otherwise bare, unsightly spots with beauty. It appears fashionable to grow upon certain choice old garden trees. Take the *Cydonia* or Quince, for example, a picturesque and charming tree, more thought of, perhaps, than of its beauty as a lawn tree, its heavy masses of bloom a picture of beauty, the heavy, rich yellow fruits filling the air with

their pungent odor. If such trees were troublesome to grow we should not express surprise at their scarcity in new gardens, but they will thrive in ordinary soil and positions. One often finds many very odoriferous flowering trees and shrubs in a common shrubbery, a kind of arrangement in which free and graceful shrubs are planted so thickly together as to spoil their true beauty. It is impossible to see their proper character, huddled up in this way, putting in a variety of things from Quincea to Mock Oranges. Each tree, shrub, or flower, should tell its own tale, and please by its beauty of form and prodigal display of blossoms. A very interesting class is formed by the Brooms, and *Cytisus scoparius* *Andreas* is very fine. We get a rich association of colour, yellow against velvety crimson, and it is quite hardy, exceptionally free, and a delightful garden shrub. Very beautiful in late May is the White Spanish Broom (*Cytisus albus*), its slender stems smothered with white flowers, a perfect mass, and such an effect may be gained easily, as the Spanish Broom is not difficult to grow, if the soil is fairly light. This reminds me that the Yellow-flowered *Genista praeox* is just as free, every shoot being hidden by the soft-toned blossom, with scarcely a leaf visible. It is such

fection. Covered with flowers in April is *Forsythia suspensa*, the shoots hung with the richly attractive blossom, a brilliant mass of yellow. This is a half-shrub, and may be grown against a wall, permitted to scramble over a sunny bank, or trained in the form of a bush. One of the most beautiful beds I have seen was of this *Forsythia*, the shoots trained over a few sticks placed in the beds for support, and covered with golden bloom, hung gracefully on the slender shoots. One may cover a low wall with it, as in the case of the *Jasminum nudiflorum*, the winter-flowering *Jasmine*, that blooms in the late autumn and winter. The Californian *Garrya elliptica*, is also a winter-flowering shrub, its light-green coloured catkins appearing in profusion during the "dark" months of the year. It is not of vivid colour certainly, but the green catkins are of quiet beauty, and may be cut for filling vases indoors. A good hush of it is an interesting winter feature, but the usual way is to plant this shrub against a wall, where its rich green foliage and abundant catkins are well displayed. I have further notes to make. V. C.

4376.—Cutting back Hollies.—Variegated Hollies that are 20 feet high will not

THE CATALPAS OR INDIAN BEAN-TREES.

THOSE who know the American Catalpa will recognise in the accompanying illustration a very fine specimen of *C. bignonioides* in full flower. As may be seen, it has long since attained maturity, and shows plainly the handsome wide-spreading head which an old Catalpa always develops when growing in a suitable soil and climate and in a sheltered spot, so that its head is uninjured by high winds. There is, in fact, no freer object on an English garden lawn than an old Catalpa, as it is beautiful in leaf and highly attractive through harvest time, when, as a rule, it is covered with a profusion of loose white flower clusters, which, in warm climates, are succeeded by a crop of long seed-pods, which look like attenuated French Beans, hence the name Indian Bean-tree. The rapid growth of this tree is a great point in its favour, for from the seeding stage to the flowering period, which occurs under favourable circumstances at from twelve to eighteen years of age, it grows on an average from 1 foot to 18 inches a year, so that in twenty years the tree has reached its full height, which in this country rarely exceeds 40 feet, unless the tree is drawn up by others. When at full height the tree develops laterally and continues to form the broad, rounded head shown in the illustration. Like other large-leaved trees, the Catalpa needs a deep, free soil for rapid and luxuriant growth, and though it will sometimes thrive on poor soils and exposed dry spots, it is never seen to such perfection as in deep, moist soil, such as the rich alluvial soil on the banks of rivers or lakes. This accounts for the existence of the magnificent Catalpas one sees in the valley of the Thames, where probably more old Catalpas can be found than in any other locality throughout these islands. The Catalpa is peculiarly a tree for very small gardens, because it never grows very large. It is, in fact, one of the few medium-sized trees that can be planted on a small lawn, and as a town tree has few equals, being, like the Plane and the Fig, especially adapted for withstanding the impure atmosphere of towns. The fine specimens we see in London, the Temple Gardens, the squares about Bloomsbury, for instance, quite prove this, and no doubt the tree is benefited by the extraneous and warmth of the atmosphere of a town affords, which tends to ripen the young wood, rendering it less liable to be killed in winter. It is fortunate that the Catalpa is one of the last trees to come into leaf in spring, for if it were early it would always be overtaken and damaged by late frosts, which, indeed, is the case occasionally. The common kind of Catalpa is the North American *C. bignonioides*, also called *C. syringifolia*, or Lilac-leaved, which was introduced to English gardens in 1726. Probably the oldest trees of it that exist here are those about London, notably in the Fulham Palace Gardens, it being one of the choicest favourites of the tree bishop, Bishop Compton, so that it is one of the earliest exotic trees introduced. *C. speciosa* differs from the other in being more erect and taller, with leaves more pointed. The flowers are larger and almost pure white, whereas in *C. bignonioides* they are tinged with purple, and spotted with yellow. The point that makes *C. speciosa* most valuable to us is its more hardy constitution, more rapid growth, and the fact that it flowers a fortnight earlier. The other two Catalpas are *C. Kampferi*, a native of Japan, and *C. Bungei*, from China. Both are modern introductions, and as far as we are able to judge from the largest trees in this country they are not likely to rival the American kinds. W.

Indian Bean-tree (*Catalpa bignonioides*).

cheap, easily-grown, and useful shrubs as these that one wants to encourage in gardens, a complete contrast to the evergreen Box or formal Laurel.

THE COTTAGE GARDEN often boasts of greater beauty than more pretentious plots, and we think it is through a mistaken notion that the things so beautiful in the country are unsuitable for the outskirts of large towns. The *Daphne Mezereum*—more often called the Mezereon—is a very easily grown shrub, the branches covered with purple bloom in early spring, the flowers scenting the garden. Two or three good bushes of this shrub are very beautiful, and in mild years the flowers open before February is over. Let the soil be light and the position sunny, then we may expect the *Daphne* to make our hearts glad with its sweet-smelling flowers, followed by crimson berries. The crimson-flowered *Escallonia macrantha* is a well-known shrub, but must in all northern districts be grown against a wall, either in the southern counties it may be placed freely in the open. I remember seeing very fine bushes of this delightful shrub in the Queen's Garden at Osborne, and visitors to the Isle of Wight who are interested in shrubs and flowers may enjoy themselves to their heart's content in the little island, as in the balmy air plants thrive to per-

stand a rough and ready treatment like younger ones. They have arrived at that age when all the specimens I have met with, even when growing under favourable conditions, decline in vigour. At the same time I see no reason why you should not deal with them in the way you suggest, providing you do the work well. The best way of doing this is to give the roots a top-dressing at once, either a layer of rotten manure, 6 inches thick, or half that depth of rich soil. The effect of this will be that the branches will break stronger when you prune them. With regard to the later operation the middle of March is soon enough. I advise you to reduce the height three feet, not two-thirds their length. One-third is as much as I can be responsible for. Even then the whole of the branches should be dealt with alike, heaving, of course, some regard to the form of the trees. The trees will be somewhat ugly after the operation, but it will only be for a few months.—J. C. C.

—The best time to cut back Hollies is in June. They might be cut back now, but they would not break before spring.—E. H.

Weevil destructive to Beech.—Referring to my letter two or three months ago concerning the injury done to the Beech by weevil, I find the name of it is *Orchestes piceae*. It has done much mischief in this neighbourhood, and it would be interesting to know if the *Orchestes* of Beeches in other parts of the country complain of it.—E. L. A.

4359.—*Choloya ternata*.—This is the Mexican Orange-flower. It is not a really hardy shrub—that is to say, it cannot be recommended for gardening of every kind. But it is surprising to see that even in northern districts, where there is shelter, it will live out unharmed. If, however, your garden is right in the south you may plant the *Choloya* without fear of destruction by frost. It grows quickly, and the white fragrant flowers, so richly scented as the Hawthorn, are in bold relief to the masses of deep-green leaves. Cuttings strike readily in the spring, and may also be put in now. One meets with more specimens in Devonshire than in any other county, but it is essential to give the shrub

shelter, therefore it succeeds best against a wall. A bush of it is very charming, and select a sunny spot to get the growth well ripened. The hardier the growth, so much the better chance the shrub has of weathering the storms of winter.—C. T.

— This is a very effective dwarf shrub for a warm situation. It produces white fragrant flowers abundantly; even small plants flower. Here, in the eastern counties, we find it necessary to plant it against a wall; but in the south or west it would, I have no doubt, do very well in the border. Give it a little leaf-mould.—E. H.

4392.—Ivy on walls.—Apart from the fact that the varieties named are not so well adapted as self-clinging kinds to walls as the Irish Ivy, for instance, the present summer being so hot and dry is not at all favourable to ivy's supporting themselves, owing to the scarcity of moisture in the bricks. After several days of successive rains the stems of Ivy plants can be seen thickly studded with white succulent roots, which is conducive to the clinging of the branches to the walls, but seldom has this occurrence been observed this year. There is nothing "ivy" can do but tack the shoots to the walls as they grow, and well soak the soil with water.—S. P.

— The best way to induce Ivy to cling is to encourage it to do so from first planting. When once naturally begins it has to be followed up and is rarely satisfactory. The plan I adopt is to peg the plants down close to the base of the wall after planting, and then they cling from the start and never need the slightest assistance in this respect.—A. H.

— Are the shoots affected with black-fly or similar pests, which would account for their behaviour? It is singular, as all the varieties named grow well, especially Emerald Gem. The only way is to keep them well watered, but if the growth is not vigorous, one could account for it.—C. T.

4393.—Onting Yews.—Better plant the Yews and give them two or three years to get established before the cutting is begun. Yew-trees will break out of old wood any time.—E. H.

HOUSE & WINDOW GARDENING.

CHINESE SACRED LILY (NARCISSUS TAZETTA) FOR A ROOM.

This is a favourite window plant, for it grows so quickly and bears such a mass of sweet-scented blossoms, that it is specially suited to room culture, besides being suitable to grow in water, if preferred. The bulbs should be procured directly they arrive in this country from China (usually early in December), and they only require eight weeks to produce their blossoms, so that they may easily be had during the depth of winter. Place them in shallow bowls, four or five bulbs in a group, with a few stones to prevent them from falling about, and a little charcoal in sticks to keep the rain-water, which should be preferred to hard water, pure. The bulbs should stand in a dark place for ten days to form their roots before starting their leaves, and they may then be transferred to the window of a sunny room with a moderate fire, where they will grow rapidly. They must not be placed in a sharp draught, however, and the morning brushing out, which necessitates both the door and window of the room being open at once, is the cause of many failures, for the owner, coming down to a comfortably warmed room at breakfast-time, fails to consider that the temperature was arctic at seven o'clock that morning, and the plants probably exposed to the full force of the wind. To avoid this danger, room-plants should be sheltered with double newspaper, which can easily be made into a sort of bell-shaped cover by the use of a little wire, over which the paper can be pasted. This prevents dust from accumulating on the leaves, and keeps out the dangerous draught, if placed over the plants at night, besides saving them from the possibly freezing effect of a sharp frost during the night. The only other safe plan is to take valuable plants into a warm bedroom at night, replacing them in the window after the morning arrangements have been completed.

I. L. R.

Roman Hyacinths for a room.—These are the earliest of all the bulbs to open their blossoms, and their graceful white flowers, fragrant, and delicate appearance, are very welcome visitors during the dark winter days. The bulbs should be procured at once, and potted

early for early blooming, putting from three to five as closely as possible in a 5-inch or 6-inch pot near the surface, and using light sandy soil, which should be fairly damp when used, when the bulbs will not require more water for three weeks. After potting they should be placed out-of-doors, standing on a layer of fine coal-ashes, and covered with the same material to the depth of 2 inches. In about three weeks' time the green points of the Hyacinth will be visible on removing the covering of ashes, and the pots may then be taken into a sitting-room, where the bulbs will quickly unfold their flowers. Bulbs potted in August blossom in November. Relays may be easily arranged by potting the bulbs at intervals during autumn.—I. L. R.

DATURA SUAVEOLENS (BRUGMANSIA) IN A ROOM.

This handsome plant, bearing large white trumpet-shaped flowers of delicious fragrance, grows so quickly to a large size that it is seldom used for room decoration. Yet it is so easy to obtain blossoms on a small specimen,

Lastrea sancta.

and these plants are so highly appreciated in the drawing-room for their handsome appearance and sweet scent, that those who have large Brugmansias should not fail to supply themselves with plenty of young-flowering stock. To do this successfully, the sturdy little shoots, which grow low on the stem of a thoroughly healthy plant, should be selected (slipping them off with a little heel), and placed singly in light soil and sand (equal proportions of each), in thumb-pots. These are best placed over a light bottom-heat, in winter, but must be covered with a bell-glass, or an ameteur can put a tumbler over each, and stand them in a sunny window at this time of year, shading them with newspaper from eleven o'clock at first. They will quickly form roots if kept damp and rather close, but the glass must be taken off and dried with a cloth daily, raising it slightly after the first day or two so as to admit a little air, which can be gradually increased. Those who have set up that most useful thing, a "cutting-box," will place their Datura cuttings

in it and find them do well—a "cutting-box" being only an ordinary wooden-box, such as can be procured at the grocer's for a few pence, about 18 inches deep, and any ordinary size according to the number of pots it is to contain. There should be a layer of fine ashes at the bottom of it, from 4 inches to 6 inches deep, and two or three pieces of broken glass to cover it; these are preferable to one whole pane as they can much more easily be arranged to give gradual ventilation if it may be needed. The "cutting-box" may stand in a window where sunshine will warm one side of it, but it must be shaded with a piece of newspaper while the sun strikes on the glass, until the cuttings begin to grow, when they can be gradually inured to both air and sunshine, and are then ready for a shift. To return to the Datura slips; they should be potted on rapidly, giving small shifts and rich soil as soon as roots are formed, growing them close to the glass, with plenty of warmth. Before they are 6 inches high, the flower-buds which were formed in them, when taken off the parent tree, will begin to show, and with thorough support in the way of liquid manure or soot-water, it is possible to have a plant of this kind not exceeding a foot in height with five or six blooms on it at once. Daturas will blossom well too in the winter if given an intermediate temperature, and are then most valuable for decorative purposes. Cuttings can be struck at the present time on the above lines if given heat during winter; otherwise it is better to wait until the early spring, when they can be grown on quickly without much fire-heat. No insect pest, such as green-fly or red-spider, must be allowed to infest them; constant syringing is the best remedy for this.

I. L. R.

Anemones for a room.—Few of our spring flowers are more charming than those of the Anemone family, whether we speak of the wild Wood Anemone or the more gorgeous varieties in cultivation. These are so numerous, and embrace such various tints, every shade of scarlet, white, yellow, violet, and even sky-blue (Anemone apennina, the blue Wood Anemone), being represented amongst them, that a collection of the varieties would be worth having, the Riviera, Ireland, France, Holland, and many other countries contributing distinct yet lovely Anemones. They are all hardy, and can be grown best out-of-doors, their pots sunk in a bed of ashes when needed for a room, so that they can be lifted into position when in flower, and replaced at any time in their ash-bed directly their blossoms are over. Any ordinary compost will suit them, with a little leaf-mould and sand, and they do not require more water than the rain provides until they begin to throw up their blossoms in the early spring, when they should on no account be neglected. A mulch of half-decayed leaves over them during the severe weather will be useful.—I. L. R.

FERNS.

LASTREA SANCTA.

THE Fern of which an illustration is given was raised from spores received from Jamaica. It has never been plentiful, but is elegant, and well deserves a place in every collection. It may be grown in a pot, or planted out in a Wardian case. The fronds vary from 3 inches to 9 inches in length, and are somewhat thin in texture; the segments are finely cut, and rich deep-green in colour. If grown in pots it should be confined to a somewhat small-sized pot, as its roots do not appear to like much soil about them. It grows freely in a mixture of peat, leaf-mould, and sand. A good supply of water to the roots is beneficial, but sprinklings over the fronds with water from the syringe are apt to turn them black. A somewhat close and moist atmosphere is necessary for the plants, and to get the full beauty of the delicate fronds.

J.

4391.—Calined bones and leather.—The calined bones are excellent; mix the floor and dusty part with the soil, in the proportion of a 6-inch potful to two bushels of soil, and use the larger pieces as drainage. About the leather I am not so sure, and should advise caution in using it, though I once had the care of a garden in which a quantity of this material was contained in the soil, and on the whole the plants grew remarkably well. Let it on a small scale first.—H. C. R.

RULES FOR CORRESPONDENTS.

Questions—Queries and answers are inserted in GARDENING free of charge if correspondents follow the rules here laid down for their guidance. All communications for insertion should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR of GARDENING, 37, Southampton Street, Covent Garden, London. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Unanswered queries should be repeated. Correspondents should bear in mind that, as GARDENING has to be sent to press some time in advance of date, they cannot always be replied to in the issue immediately following the receipt of their communication.

Answers (which, with the exception of such as cannot well be clarified, will be found in their different departments) should always bear the number and title placed against the query replied to, and our readers will greatly oblige us by adding, as far as their knowledge and observations permit, the correspondents who seek satisfaction. Conditions, titles, and means vary so infinitely that several answers to the same question may often be very useful, and those who reply would do well to mention the localities in which their experience is gained. Correspondents who refer to articles inserted in GARDENING should mention the number in which they appear.

4407.—Gladioli from seed.—Could you give me full instructions on how to grow Gladioli from seed?—ORIGINAL.

4408.—Melons splitting.—Will someone say what is the cause of Melons splitting, and if there is a remedy?—R. L. A.

4409.—Cox's Orange Pippin.—At what time is Cox's Orange Pippin usually ready to gather in the south?—R. L.

4410.—Siberian Crab preserve.—Could you give me a good recipe for making a preserve of Siberian Crab-Apple?—J. H. S.

4411.—Stonecrop for rockery.—Whatever the best kinds of Stonecrop for a rockery facing east, and the time to plant them?—A. NOVICE.

4412.—Woodlice v. Mushrooms.—Can anyone kindly tell me the best way of getting rid of woodlice from a Mushroom-bed?—H. F. W.

4413.—Nettles on a farm.—I shall feel much obliged if you can give information as to the best way of exterminating Nettles on a farm?—J. R. A.

4414.—Onion-fly.—Will you please tell me the best preventive for Onion-fly? My gardener tried sprinklings of paraffin for the spring crop, but it was of no avail.—D. KOKK.

4415.—Parsley.—My Parsley has been very fine, but has recently turned brown. It is quite spoiled for use. Can you tell me the reason, and how to prevent it, in future?—BURKARD.

4416.—Tea Roses.—Will someone kindly give me the names of some large-flowering Tea Roses, such as Grace Darling, L'Idéal, Vicountess Folkestone? I want some with large flowers.—R. A. T.

4417.—Caterpillars on bush fruits.—Can anything be done to prevent the caterpillar plague on Gooseberry and Currant-bushes? If so, what time of year will it be best to treat them?—H. S. E.

4418.—Mountain Ash berries.—Can you or any of your readers kindly inform me how I could preserve Mountain Ash berries in bunches for church decoration at Christmas? An early answer will greatly oblige.—M. G. T.

4419.—Roses for north border.—What Roses would you recommend for a garden towards the north, and getting, therefore, a limited amount of sunshine? I am not skilled in their culture, and would desire hardy kinds that give a good quantity of bloom.—ASPIRANT.

4420.—Pears.—I shall be glad if anyone can tell me whether the following Pears should be left to ripen on the trees or picked unripe: Duchesse d'Angoulême, Pitmeston Duchesse, Dr. Troessem, Josephine de Malines, Duchesse of Brabant, Knight's Monarch, Maréchal de la Cour.—C. H. MOUTH.

4421.—Fuchsias.—Will you kindly tell me what to do with six-year-old Fuchsias that have rather gone to wood? They flower well, but only at the top of the plant. Should they be cut down, or thrown away? The leaves of some of the plants are like two. What should be done with them?—J. C. IMPER.

4422.—Hedge of Gooseberries.—I am anxious to form a hedge of Gooseberry-plants on the cordon principle, each plant having not more than three branches which would be trained on wires. Can anyone tell me where I can obtain such plants of a bearing age, of the sorts Red Warrington, Red Champagne, and Early Sulphur?—R. L.

4423.—Roses against a wall.—Three weeks ago I was asking your advice about a Gloire de Dijon Rose. It is against a wall 6 feet high. Now the growth this year is so strong that the shoots in some cases are 2 feet above the wall. I want to know if I should cut them or just nip the top to keep them from growing any higher?—ROWLAND BAYLOR.

4424.—Budding Roses.—Will some reader kindly give the following information: 1. What stage of growth ought the bud to be? 2. When budding low down to avoid suckers it is necessary to return the earth removed, and, if so, would the earth not then injure the bud, which, of course, would be covered by it, or should the bud be left bare?—B. S. EGON.

4425.—Begonias in the garden.—It would be interesting to have the opinion of some of your readers on Double Begonias as bed and border plants. I find I can grow them equal to the finest snow flowers, but after three or four fine flowers they deteriorate, and become worthless in my opinion. They are grown under very favourable circumstances.—W. C.

4427.—Sulphur in a greenhouse.—I have a small greenhouse which has a fine with brick sides, but when it is lighted the sulphur fumes escape. I should be glad if any reader of GARDENING will tell me what I can do to prevent the sulphur escaping? Would a thin coating of cement on ordinary mortar be suitable? If so, how should it be made?—STEPHEN JOHNS.

4428.—Sowing annuals.—Would it be safe to sow now in a cold district of Fife-shire, Scotland, seeds of Shirley and French Poppies, Marigolds, Collinsia bicolor, Erysimum Peroffkianum, and Chrysanthemum segetum? Self-sown Poppies, and the last named annual came up year after year, and I think all might be had in flower earlier if sown now, but would they stand the winter?—ZOMIE.

4429.—Gas-line and wireworms.—I have some two acres of newly-broken up pasture land, on which I have grown a crop of Potatoes which are eaten through and through with the wireworms. Could any of your readers tell me the amount of gas-line that can be safely used this autumn to per rod of ground, so that the crop next spring will not be injured by its use?—PERKINCE.

4430.—Passion-flower in fruit.—I have a Passion-flower, a very large plant that is every morning a mass of bloom, and is now becoming so laden with fruit (which are very large) that it is being broken from its fastenings. Is it not rather unusual for these flowers to fruit so freely? Is there any market value for the fruit? Have you or any of your readers "preserved" any? I am told they are not very good eating.—ALPHEA.

4431.—Lilium auratum.—I have received a number of bulbs of the above in pots, the stems of which have just been cut down to within 6 inches of the soil. I propose leaving them undisturbed, keeping just moist until November, and repotting in suitable compost and a six-larger pot. Will you kindly inform me whether I can improve upon the treatment, and can I reasonably look forward to good blooms next year?—G. H. W., West Brighton.

4432.—Rose W. A. Richardson.—I have a Rose-tree W. A. Richardson, now two years old. It has grown to the height of 10 feet, and about 2 feet clear. I planted it 2 feet from wall, and trained it up two pieces of wood. It has never been pruned. House faces south-west. The Rose is most irregular in shape, and they burst into full bloom very quickly (in a few hours). Instead of opening at the top, they burst out of side bud. It has been well watered and manured.—THOS. ROBINSON.

4433.—Manure for Roses.—What manures are best for Roses? I see diluted horse slops, horse droppings in water, a little soot, plenty of stable and pig-stye manure twice a year as a mulch, and seed-cups from the weekly waste of the house, and so on. How applied? Mine roses are in a sandy soil, with old turves in many places, and I am planting. Is disbanding of service in increasing size of blooms? It never seems to make mine larger. What are the cream of the H. P.'s for exhibition, twenty-four varieties?—A. ROSE & J. J. J.

4434.—Water Lilies.—Many years ago I had a small tank made of brick and cement, and about 6 feet 7 inches in diameter, inside measurement, and about 2 feet 8 inches in depth. When it was made I covered the bottom with some loamy soil, and put fine gravel and sand on top of it. I put roots of common White Water Lilies, Nymphaea alba, in soil. They grew and flowered remarkably well until the last two or three years, when they have not done so well. As the roots are not so small as I thought they might be overcrowded. About 12 months ago I emptied the tank, and took roots out and divided them, but with no better result, as they are flowering poorly still this season. Would "A. H." inform me?—K. W.

4435.—Culture of Roses for exhibition.—I grow Roses, and having taken first prizes at local shows, am ambitious of exhibiting next year at larger centres. Will your contributors, "J. C. C." and "P. V.," give me the benefit of their valuable advice how to prune and manure, and also what sorts to choose for the highest competition? I have now about 250 plants in almost as many varieties. Very few of them are of sufficient size to gain premier honours outside my local radius. I thought of adding six varieties of Teas, and six varieties of H. P.'s in about three plants of each sort, making separate beds in an old pasture for them and pruning severely for exhibition bloom alone. Would those six varieties in each class be sufficient as I have all my general rosery to go to until the last six to make the necessary twelve blooms? Can this selection of Teas be improved upon for size and form: Countess of Nedalim, Jean Ducher, Niphator, Maréchal Niel, Hon. Edith Gifford, Madame Lambert, Madame Heete, Catherine Mermet, Françoise Kruger, Amazon, Madame Oharrie, Marie Van Houstele. The thin fragile ones like Souvenir d'un Ami, Rubens, Socrates, Marquise de Vivens, and others, spoil season with weather and only open quickly to great benefit. Ought I to prune Teas hard as well as H. P.'s for exhibition bloom? Usually they get no further pruning than cutting away the dead wood killed by frost in the winter, together with any weak spray.—A. ROSE & J. J. J.

To the following queries brief editorial replies are given; but readers are invited to give further answers should they be able to offer additional advice on the various subjects.

4436.—Hemerocallis (Mrs. Youl).—The reason is no doubt that the Lilies are too rich a soil. They require only a rather poor ground, and would run to leaf in the staple as mentioned by you.

4437.—Roses mildewed (J. B. S.).—The leaves of the Rose-bushes are unquestionably affected with mildew. Duet them with flowers of sulphur. There is really no other remedy, and some kinds are more affected than others.

4438.—Climax (Gloxinia).—The plants were evidently kept too hot and close. Sylling or watering has been done with the sun upon them, and the result is the foliage has got scorched. This seems to be the cause of the mischief.

4439.—Gaillardias in winter (Anxious).—If the soil is wet, the position cold, it would be best to protect them, but in warm situations in the more southern countries they live out unharmed. If in pots keep them in a frame until the spring.

4440.—Storing Apples (Enquirer).—Keep them in a cool, dry room, and lay the fruit out in single layers. Do not keep them up. An even cool temperature is the chief point to consider. Be careful in gathering not to bruise any. Every bruise will develop into decay later on. Go over the fruits every two days at least, and use those that do not appear likely to keep.

4441.—Epidendrum nemorale (J. R.).—The imported plant you send from Mexico may perhaps of this species. The bulb is very much in the way of E. nemorale, and if so, and you are successful in flowering it, then you will be well pleased with them. It is a most attractive plant when well bloomed, but you have got them home very late in the season.

4442.—Hyaonthis candicans.—H. Walton says he has this very fine, growing in the centre of a bed of slow-Rhodes grass. It is a plant that should be used by everyone having a garden, big or small, for its tall spikes of large waxy-white bells are indeed very lovely. I would suggest deep planting as one of the chief requirements for securing it in the open border or garden.—J. J.

4443.—Cannabis sativa (T. K.).—This is the scientific name of your specimen, and its English name is the hemp-plant. It is an annual which, when well grown, makes an elegant subject in the border. It grows about six feet, or even ten or more feet high. From the dried leaves of the Cannabis the Indians make an intoxicating drink called Ebeng. It is a first-rate subject for London gardens.—J. J.

4444.—Plants for garden (Aspirant).—All the things mentioned may be planted in the autumn, late September or early October. You need not be idle, but get the ground ready at once. If it is poor, it must be liberally manured and thoroughly trenched up. If the garden is quite new, in fact, has to be formed, let there be a flower-bed in the centre, and keep the walks to the outside. In a very small garden it will not be necessary to have a walk at all. Let it be Grass and flowers.

4445.—Hemantus coccinea (Renfrewshire).—Spring is the time for planting these bulbs, and use a soil composed of loam and peat, equal parts, mixed with sufficient silver-sand to make it moderately light. They will succeed in a warm greenhouse temperature, and water should be sparingly given until they are in full growth. The bulbs may be wintered in a temperature of 45 degs, but must not be exposed to frost. Water should be gradually withheld as they go to rest.

4446.—Odontoglossum Lindleyanum (D. Blackburn).—I can only say that this is the species you show, and I am still more sorry to find that such a poor and common thing was named after the man to whom Botany owes so much. You should certainly keep it for its name, but if you have many of the same species, dispose of them to the best advantage as soon as you flower them. I should advise you to bloom them at first, because you may have some good hybrid. Send the dried flowers out to the party that sent them home, and tell him that you do not require more of these.—M. B.

4447.—Porekia aculeata.—P. Wilson asks what he can do with this plant, which climbs about like the Bramble, and never flowers. It was given him some years ago for a Cactus. Yes, it is a member of the Cactus family, which is popularly known by the name of the "Barbadoes Gooseberry," and it differs from the rest of the family by having two leaves. If you have it you will rather in the greenhouse you should graft it in various places with Epiphyllum, and in this way you will find it most to use. I do not like this plot for a stock for working Epiphyllum upon. The stems of Cereus apiculatus are very much better.—J. J.

4448.—Calanthe turning black.—T. W. M. sends some bulbs of this plant, "which have turned black as if from some form of canker." It appears to me that although you are not a young beginner in the cultivation of these plants, you have started wrong. "T. W. M." says he bought two dozen, but in the winter from a person that was hired of Calanthes, and he obtained them for a few shillings. I cannot tell for certain what is the matter with them, neither can I say why your friend had got tired of Calanthes, but I should suppose it was through having got this cankerous disease into them, which appears to me to be the result of the applications of liquid-manure. I have noted this disease to set in, and frequently take years to get rid of, when the plants have been subjected to large doses for a few years. My advice is not to give them liquid-manure. Your treatment appears to be quite right.—M. B.

4449.—Cypripedium cardinale.—W. W. sends me some of the last flowers of this kind, which he says "have been produced from the plant without its now being out of bloom since the 9th of March last. It is one of the hybrids raised by my old friend, Mr. Seden, at the Messrs Veitch's establishment, and it is one of the Selene pedunculata, or South American crosses. C. Sedeni, itself a cross, and C. Schlimi albidiflorum. It retains the bright colour of the lip of the first named plant, whilst the outer segments are like that of the last, having in some instances a slight tinge of pinkish-sepia, whilst the lip is bright rose. It is very curious that although these are American kinds intercross with each other readily and flower freely, I do not remember to have seen one between the Indian and American kinds, neither have I seen one instance of the North American plants being used. These hardy Lady Slippers are certainly so worthy of attention as the tropical kinds. They would serve to enliven and beautify the rockeries and borders in our gardens.—M. B.

4450.—Chrysanthemums (A. M. H.).—The following are the classes to which your Chrysanthemums belong: Mrs. Gibbons, Mrs. H. H. H., H. H. H., Florence Davis, E. Molanux, Sunflower, Standard White, Gloire de Reuter, Louis Robeur, Vivand Morel, Gloire-de-Paris, W. Tucker, Baron de Bally, Standard Surprise, Queen of the West, Peter the Great, and W. H. Robinson are James, Paul, and Andrew and Makler's

Blush are known as Japanese reflexed. John Doughty is an inquirer of the "Queen" section, a sport from the original Queen of England, and is the same as Mr. Robert Mudie. La Ohlani I do not know; perhaps you mean La Chloise, a dark crimson Japanese flower? Any buds that form now should be "taken"; if they were rubbed off the blooms produced from the shoots made consequent on the removal of the buds would be late, and the flowers would be small. H. W. Tucker, John Doughty, Maiden's Blush, and Val d'Auderré showed buds at the early part of the month I should rub them off, and wait for the next. The shoots on these sorts will have advanced somewhat already.—E. M.

NAMES OF PLANTS AND FRUITS.

Names of plants.—*J. W.*—The *Celandine* (*Chelidonium majus*).—*J. Mc. Leish*.—1, *Aspidium bulbiferum*; 2, *Lomaria nuda pulcherrima*; 3, *Litobrochia uncaelata*; 4, *Cystopteris Fontinalis*; 5, *Polypodium angulare perississimum*; 6, *Selaginella citrinella*.—*C. Cameron*.—1, *Rhynchospora alba*; 2, *Cyperus sclerifolius*; 3, *Elymus scicolaris*; 4, *Onoclea sensibilis*.—*J. B. R.*—*Tradescantia procnisa*.—*C. R.*—*Periploca grœca*.—*O. Arbuthnot*.—1, *Erechtia serrulata*; 2, *Rumex* (*Banarizina officinalis*).—*W. H. R.*—*Phalox Cooksoni*.—*Aubors*.—*Silvery-leaved Poplar*.—*Belle Vue*.—*A. Catasetum*, probably *C. Bungeoides*; but it is difficult to tell from a small dried flower. —*Amateur*.—*Oncidium incurvum*.—*Pills*.—The *Hawkweed* is *Hieracium aurantiacum*.—*G. H. S.*—*B is Baby*. The others we do not recognize. —*W. H.*—Do not recognize it. It is a most objectionable colour, and not worth growing. —*W. Lloyd Jones*.—Do not name florists' flowers. It is impossible to be correct. —*A Constant Reader*.—*Campanula carpatica*.—*J. W. A.*—*One of the Correas*.

Names of fruit.—*F. Richardson*.—*Apple Wellington*.—*C.*—The fruits were not only rotten, but positively objectionable through being packed in a carbolized box. Seed decent example, and we shall be pleased to name them. —*R. E. G. L.*—1, *Pear Beurre d'Algeron*; 2, *Cox's Orange Pippin Apple*; 3, *Fearo's Pippin*; 4, *Probably Galin*.—*D. D.*—The fine red Apple is *Emperor Alexander*. (A) *Pear Napoleon*. (B) *Marie Louise*.—*A. B. H. J.*—The old Five Crown Pippin. —*X. Y. Z.*—1, *Warner's King*; 2, *Harcourt*.—*F. D. S.*—*Apple Red Astrachan*.—*Burton*.—*Williams' Bon Chrétien*.—*H. P.*—1, *Williams' Bon Chrétien*; 2, *Napoleon*; 3, *Fondante d'Automne*.

Name of vegetable.—*J.*—*Potato*, probably *White Beauty of Hebron*. It is not easy to tell from a single tuber, they run so much alike.

TO CORRESPONDENTS.

We should be glad if readers would remember that we do not answer queries by post, and that we cannot undertake to forward letters to correspondents, or insert queries that do not contain the name and address of sender.

Mrs. Blackett Ord.—The decayed Peaches are probably due to a want of lime in the soil. Incorporate lime with the staple. —*A. L.*—Please send specimen of leaf. Your description is too meagre. —*One in a Fix*.—Fork them up, as the weeds are then thoroughly eradicated. —*J. Clark*.—Many thanks for your list, but we have already given the names of very fine varieties. —*H. S. C.*—It is the result of the severe drought and ascessive heat. You must water the plants liberally. —*Rat*.—We think *Tropæolum tuberosum*, or some other kind is intended. —*W. M.*—Yes, the leaves would do very well. They are not the best for the purpose, but will do to mix with the others. —*Nevils*.—Do you mean under glass? It is too late to plant now in the open. —*Creditor*.—Of course you are wrong. A collection of 12 kinds, or merely a collection, signifies distinct varieties. —*K. L. G.*—You get the plants cheap. —*Guy Attwood*.—The Peaches look all right, but they are eaten by wasps, or some other pest. It is the variety that is at fault. One fruit was tasted was ripe, and of very poor quality. —*W. Thomas*.—We are not sure that the work has been revised, and, if it has, not by the gentleman mentioned. It is rather a cumbersome volume. Before purchasing tell us what form of gardening you require information on. If you require the book simply for the library, purchase it. —*A Novice*.—Better get some good clumps, if possible. They are not expensive. Plant them in the autumn. —*R. C.*—Gather the fruit about mid-September. You can easily tell whether they are ripe by the way they part from the stalk. —*X. Y. Z.*—Due to the intense heat. About 45 degs., not less, for the hour.

BIRDS.

4451.—*Goldfinch mule*.—I have a Goldfinch mule, six years old. Two years since, when moulting, I observed a bare yellow, wart-like spot at root of tail, which has so remained till this season it has spread all over the back. Can you suggest cause and remedy? It is fed on *Cheary*-seed and *Capern's Mixture*, and seems quite well and really, singing as usual. —*D. R. LAMP*.

4462.—*Bullfinches losing new feathers*.—Will you tell me the reason of my young Bullfinches losing their feathers? They are about 3 months old, and were just changing their colour, but now all the feathers are coming out of breast. The skin is very red, and they scratch themselves with their feet as if something bit them, but cannot see anything. They are kept very clean, and are fed on *Hemp*-seed and green *Groundsel*, &c. Advice what to do with them will be welcome. —*CONSERVAT READERS*.

"Gardening Illustrated" Monthly Parts.—*Price 6d.*, post free, 8d.
 "The Garden" Monthly Parts.—This journal is published in neatly bound Monthly Parts. In this form the coloured plates are best preserved, and it is most suitable for reference purposes to the issues of the half-yearly volumes. *Price 1s. 6d.*; post free, 1s. 9d. Complete sets of volumes of THE GARDEN from its commencement to end of 1892, forty-two vols., price, 30s.

"Gardening" Photograph Prizes.

LIST OF AWARDS.

We have to thank our readers for kindly sending so many interesting photographs, to which we have done our best to do justice. The competition was brought to a close too early to allow of outdoor flowers and fruits and vegetables being studied, and, therefore, in the next column will be found further prizes offered for certain classes of things during the present season. A few words as to the causes of failure. These were mainly a want of clearness and, in many cases, excessive blackness, and sometimes from the photos having little or no relation to gardens or gardening. Some have failed, too, from sending photos of very common things, such as *Lilium auratum*, of which we already possess a good many hundred photographs. For the rest, we have to thank most heartily the successful competitors, who sent us many beautiful houses and gardens, beginning with the forty beautiful studies of country houses, by the winner of the prize in this section.

COUNTRY SEATS AND GARDENS: The Prize is awarded to *Mr. John L. Robinson, R.H.A., Architect & C.E., 193, Great Brunswick Street, Dublin*, for a noble series of photographs of old English country houses.

GENERAL GARDEN AND PLANT PHOTOGRAPHS: First Prize to *Miss E. A. Willmott, Warley Place, Great Warley, Essex*.

Second Prize to *Mrs. Martin, Bournbrook Hall, Birmingham*.

Third Prize to *Mr. J. C. Smith, Nandana, Penrith*.

FLOWERING PLANTS: First Prize to *Miss E. A. Willmott, Warley Place, Great Warley, Essex*.

Second and Extra Prize to *Mrs. Newman, Hazelhurst, Haslemere*.

BEST GARDEN FRUITS: First Prize to *Mr. Norman Blake, Belford*.

BEST VEGETABLES: First Prize to *Mr. Norman Blake, Belford*.

EXTRA PRIZES:

Mr. J. T. Hopwood, 5, Bury Street, St. James, S.W. Photographs of fine old country houses. *Miss E. A. Willmott, Warley Place, Great Warley, Essex.* Two photographs of country houses.

Miss Mabel Oaisford, The Grove, Dunboyne, Ireland. Two photographs of *Olustor Rose* and group of *White Martagon Lilies*.

Mr. G. P'aneon, 32, Winalade Road, Upper Clapton, Two photographs of *Forns*.

Miss Armstrong, 5, Olifton Terrace, Monkstown, Dublin. Two photographs of groups of *Roses* and *Madonna Lilies*.

Mr. C. Mayor, Holmwood, Paignton, Devon. Four photographs of hardy fine-leaved plants.

Dr. Hemphill, Oakville, Clonmel, Ireland. Photograph of view in his garden and *White Currants*.

Miss Clara M. Wardlow, 62, Emors Park, South Norwood. Two photographs of *Madonna Lily* and *Purple Iris*.

Miss Ellen L. Cole, Elmfield, Streetbam, S.W. Photograph of *Beurre d'Amanlia Pear*-tree in full bloom, and *Maiden's wreath* on lady's head.

Mr. Baden Benger, Kuntstorf, Chester. Four photographs of *Lilium speciosum*, *Lilium tosta-cum*, *Cactus*, and *Delphinium*.

Mr. W. Bell, Leicester. Three photographs of *Silver-leaved Begonia*, *Panoum variegatum*, and view in a fernery.

Miss Edith Thompson, Stobars Hall, Kirkby Stephen, Westmoreland. Two photographs of *Sweet Williams* and *Clematis Albert Victor*.

Mrs. Martin, Bournbrook Hall, Birmingham. Two photographs of *Epiphyllum truncatum* (pink), and the *Royal Fern*.

Mrs. Stafford, Waldeck, The Ridgeway, Enfield. Photograph of *Trachelium cœruleum*. *Mr. Martin J. Harding, Lexden Gardens, Shrewsbury.* Two photographs of porch *Roses* in full bloom, and *Carnation*.

Major Arthur Terry, Walton-on-Thames. Photograph of *Pelargonium*.

Miss Crose, Clarkton Road, Wisbeach. Photograph of *Evergreen Honeyuckle* over porch in small garden.

Mr. Isaac Bealey, Mount Pleasant, Hazelgrove, near Stockport. Two photographs of view in *Tomato-house* and of *Cucumber-house*.

Rev. Henry J. Fuller. Photograph of garden of the *Vicarage, Bexley*.

Mr. S. Bowen, Lansdowne, Millbrook, Jersey. Photograph of *Wistaria* in a *Jersey garden*. *Mrs. J. W. Simcox, 20, Waterloo Street, Birmingham.* Photograph of *Kelway's Delphinium*.

Mr. J. Mayle, 133, Parliament Street, Derby. Two photographs of *Plum Cishorne* and *Fig Brown Turkey*.

Miss Lucy Bethell, Newton Kyme, Tadcaster. Two photographs of country houses.

Mr. F. M. Rammel, 34, High Street, West End, Sittingbourne. Three photographs of fruit.

Mr. James Sharp, Fiechden Cottage, Tenterden. Photograph of vegetable.

NEW PHOTOGRAPHIC COMPETITION FOR 1893.

Owing to the early date at which our prizes were announced to be sent in this year there was not time to properly take many kinds of outdoor fruits, flowers, and vegetables: therefore we offer further prizes for these things, to be competed for during the present year; allowing till the end of November for the work.

Class I.—FLOWERING PLANTS.—A prize of FIVE GUINEAS to the sender of the best collection of photographs of flowering plants grown in the open air or under glass. This series may include flowering trees and shrubs of all sorts.

Class II.—BEST GARDEN FRUITS.—A prize of FIVE GUINEAS for the best collection of photographs of any of our good garden fruits: Grapes, Peaches, Apples, Pears, Plums, or any other fruit grown in Britain. Fruits should not be crowded in dishes if good and clear photographs are sought.

Class III.—BEST VEGETABLES.—A prize of FIVE GUINEAS for the best collection of photographs of best garden vegetables. The object of this is to get fair representations of the finest garden vegetables under the old genuine names. We do not want to exclude real novelties when they are such. In all cases the name of the variety should be written on the back of the photograph.

Class IV.—AUTUMN FLOWERS AND LEAVES.—A prize of FIVE GUINEAS will be given for the best series of photographs of autumn flowers and leaves in the house in a out state for vase, table, or other kind of indoor decoration.

WHAT TO AVOID.—*Out flowers or plants should not be arranged in vases with patterns on them. Backgrounds should be plain, so as not to come into competition with the beautiful flowers. Figures of men or women, barrows, watering-pots, rakes, hoes, rollers, and other implements, iron railings, wires, or iron supports of any kind, labels, and all like objects should be omitted. Dwarf flowers are ineffective when taken directly from above. The camera should be brought low down for such. All photographs should be mounted singly, and not several on a card. The photographs should not be less in size than 5 inches by 4 inches. The following are the rules to be observed by all competitors:—*

In any of the departments, if no collection of sufficient merit be sent in, no prize will be awarded. All competitors not winning a prize will for each photograph chosen receive the sum of half-a-guinea.

These photographs may be of objects in the possession of either the sender or others; but the source whence they are obtained must be stated, and none sent the copyright of which is open to question. There is no limit as to

number, and no fee to pay. The Editor is to have the right of engraving and publishing any of the chosen photographs.

Number.—The name and address of the sender, together with the name and description of the object shown, should be plainly written in ink on the back of each photograph.

TRICKS.—All communications relating to the competition must be addressed to the Editor of GARDENING ILLUSTRATED, 37, Southampton-street, Strand, London, W.C., and the class for which the photographs are intended should be marked on the parcel, which must also be labelled "Photographic Competition." All competitors wishing their photographs returned, if not successful, must enclose postage stamps of sufficient value for that purpose.

POULTRY & RABBITS.

QUERIES.

4453.—Fowls ailing.—Will "Doulting" kindly tell me the reason of my fowls making a curious noise, like a cough, and is there any remedy, or is it best to kill them? They are in good condition and have laid very well for the last five months.—IVY BANK.

4454.—Breed of poultry.—Would "Doulting" kindly answer these questions? 1, What is the best breed of poultry for table only? 2, What are the best breeds for table and laying purposes? 3, What breed makes the best mothers?—B. C. M.

REPLIES.

4313.—Chickens losing feathers.—"E. B.," I expect, refers to fullgrown fowls, not to chickens of the year, for it cannot be possible for chickens "to be losing their feathers on and off for a year"—that is, after they have reached their full size and adult plumage, because they are then arrived at maturity, and are therefore cooing and hens as the case may be. If I am right in my surmise, the loss of feathers is due to the plumage being attacked by the birds themselves—in other words, they have taken to the habit of feather-eating. The information supplied by the querist confirms the view I have taken. I always look with suspicion upon fowls which are kept "in runs at the bottom of a garden, and in a town," even when they are well supplied with food and green stuff, and are otherwise well-managed, because fowls have nothing to do when kept in confinement. They are therefore likely to resort to bad practices merely for the sake of something to occupy their attention. It is in this way that feather-eating mostly begins. Active fowls are those which are most addicted to the practice, and my impression is that the habit is sometimes transmitted from parent to offspring. I have also known hens to be most inveterate feather-eaters one year and not to trouble about it the following season. As regards a cure, I can recommend nothing which will be permanent in its effect. Cutting the edge of the upper part of the beak will check the fowls, but as soon as the horn grows it must be again trimmed. Supply the birds with green stuff; dig over their runs and bury the corn so as to give them trouble to find it, and anoint the bare patches with vasoline. The scot and butter dressing answered because of the bitter taste imparted by the former ingredient.—DOULTING.

4317.—Powl with a red skin.—I should expect a fowl of any breed to show a red skin if his feathers were plucked off by another bird or by himself, as the constant irritation produced by the skin being pulled would be certain to leave its mark. It is scarcely likely that this is the cause of the legs turning, and I attribute the latter to the age of the cock. All fowls change their colour slightly as they grow older, and this applies as much to the skin as to the feathers. The bright yellow legs are never shown off so well in after life as in a bird's first season. I advise "E. L. T." to let matters take their course. He can do no good with dressings of any kind.—DOULTING.

Stale bread for fowls.—Where fowls are kept stale bread should never be allowed to be wasted or be thrown into the pig-tub. It should never be permitted to become mouldy, or even hard, but as soon as it becomes evident that the bread will be unacceptable to human beings put it in the fowl-house and pour holling water over it. The next step will be to mix meal with the soaked bread, and give the whole as the morning feed to the laying hens. Stale bread soaked in beer or milk is a good change for chickens, but soaked in water is bad. It will not however, do any harm to old birds, but rather the reverse.—D.

G. HAYWARD F.R.H.S.

CRYSTAL PALACE HORTICULTURAL WORKS, 80, FOXBERRY ROAD BROCKLEY, LONDON.

This is Hayward's No. 1 and No. 2.

No. 1 Span-roof and No. 2 Lean-to Greenhouses are prepared especially for amateurs, made of Best Red Deal, thoroughly seasoned, complete with Ventilators, Door, Stages for plants, Painted one coat, 16-oz. Glass, all necessary Iron-work. Delivered and packed free on rails at the following prices, satisfaction guaranteed. Write for New List.

Table with 4 columns: No. 1 Span-roof, No. 2 Lean-to, 7 ft. long 5 ft. wide, 8 ft. long 5 ft. wide, 9 ft. long 5 ft. wide. Prices listed in shillings and pence.

For other sizes and prices write for Illustrated List to G. HAYWARD, BROCKLEY, S.E.

JONES & ATTWOOD IRONFOUNDERS, STOURBRIDGE.

"DESIDERATUM" HEATING APPARATUS. Jones' Tracing, "Heating by Hot-water," 120 pages, 50 engravings. Cloth, 2s.

ORCHID PEAT.

PREPARED ready for use and in blocks; also RHODODENDRON PEAT, PEAT MOULD, LEAF MOULD, LIAIS, and POTTING COMPOST. For Price List apply to The Forester, Jordan Wood, Boxley, Kent.

Suitable for Gardens, Oricket, or Camping-out purposes. Forty feet in circumference, pure linen, with legs, poles, and lines complete. These tents are white, and have only been used a little by Her Majesty's Government, and cost over 25 each. I will send one complete for 30s. Can be sent on approval.

HY. J. GASSON, Government Contractor, RYE, SUSSEX.

G. W. RILEY, HERNE HILL RUSTIC WORKS.

81, Dulwich Road & Norwood Road, HERNE HILL, LONDON, S.E. Ten minutes by L. & D. Railway from City and West End. WORKS CLOSE TO STATION.

THE LARGEST MANUFACTURERS OF RUSTIC SUMMER HOUSES & RUSTIC WORK IN ENGLAND. Large stock always on hand from 23 10s. upwards, carriage paid, or delivered and fixed in London and suburbs. IN-SECTION INVITED. Send for New Catalogue, 17 pages, 8 stamps. Orders by Post punctually attended to. These Houses can be fixed in half an hour.

TANNED GARDEN NETTING.—Elastic Netting, Tiffany, Will make Rot-proof Berms and Canvases, Archaical Mats, Raffles, Garden Tents, Flags, Rick Cloths, &c. Send for samples and prices to JOHN EDGINGTON & CO., 19 Long-lane, West Smithfield, London, E.C.

GARDEN NECESSARIES.—Virgin Cork, 12 in. x 12 in., 17s.; 56 lb., 10s.; 28 lb., 6s. 6d.; 14 lb., 3s. Rambo cones, 4 feet, 3s. per 100. Tobacco-paper, strong, 1s. 6d. per 100. Vapour cones, 14 in., and 16 in. each. Raffles, 1s. 6d. per 100. Double-braze in, 3d. each. Manures, Best Garden Manure, 1s. 6d. per 100. Price List on application. WATSON & SCULL, 80, Lower Thames-street, London, E.C.

TRELLIS TRELLIS

- Superior planed extending
The new ornamental half-round
Cheap and durable
For all training purposes
For tennis-courts
For fowl-runs
For garden bordering
For the fruit and flower garden
For unsightly corners

FORDHAM'S, LONDON, N.

GREENHOUSES.

Intending purchasers should send for our new Illustrated Price List of Greenhouses, &c., complete from 42s., post free, 3 stamps.—S. HARTLEY & CO., Horticultural Builders, Valley-street, Windhill, Ripon, Yorkshire.

EARLS COURT EXHIBITION.

EXHIBITION OF GARDENING AND FORESTRY. The Garden of London. AUGUST 23rd and 24th.—GREAT SHOW OF AUTUMN FLOWERS, DAHLIAS, and HARDY FRUIT. Full particulars from Mr. E. E. Milner, the Chairman, at the Offices of the Exhibition, Earls Court, S.W. ADMISSION to the Exhibition Building, Flower Show, and the Central and Western Gardens, and to one of the 2,000 free seats at Captain Boyer's World's Water Show, ONE SHILLING. OPEN DAILY from 11 a.m. to 11 p.m.

EVERYONE WHO HAS A GARDEN, GREENHOUSE OR WINDOW BORDER SHOULD READ A PAMPHLET, POST FREE.

HOW TO INCREASE THE FRUITS OF EARTH.

By G. H. FITZ, F.R.S., F.G.S. Trinity Col., Dublin. Contains full particulars of very remarkable discoveries relating to Plant Life. Shows how crops of vegetables may be largely increased, lovely flowers grown to perfection, and fruit trees made to bear in any season. Selection from Hundreds of Testimonials. Post free from

JAKEMAN & CARVER, Printers, Hereford.

GREENHOUSES, Cheapest and Best.—Lean-to, complete, from 42s. Span-roof, 56s. Strong Garden Lights, painted and glazed, 4 by 3 ft., 6s. each; 5 ft. by 4 ft., 8s. 6d. each. State sizes, and obtain estimate free.—SHEPHERD & SON, Daventry-road, Shepherd's Bush, London. Catalogue post free.

PEDIGREE SUSSEX CATTLE (Gravetye Herd).—The Sussex cattle are growing steadily in public favour, both in this country and in America, where a few years ago a steer of this breed from the Gravetye stock lost at Chicago. Choice Cows and young Stock of the best blood for sale. This herd never got up for show, but kept under the most natural conditions possible. Inspection invited. Address, BAILIFF, Home Farm, Gravetye Manor, West Hinstead, Sussex.

NETTING for Tennis Bordering.—Good colour and specially prepared, with line attached to net, top and bottom, throughout. Easy to erect or to take away, 35 yards long, 3 yards wide for 7s. 6d., carriage paid.—HY. J. GASSON, Net Works, Epsom.

GREENHOUSES! GREENHOUSES!

All intending purchasers should call or send to the Royal Arch Horticultural Works, Hereford. The principal builders to all the Nobility, Gentry, and Nurserymen in Yorkshire and surrounding districts. The best and cheapest makers in the kingdom. Catalogues, post free, Two Stamps.—W. ANDERSON & CO., Fritcham, Hereford.

BALSAMS AND THEIR CULTURE.

I HAVE seen at flower shows very good plants of Double Balsams, which is evidence that a favourite flower of forty years age still has admirers. In such things as Zonal and Ivy-leaf Pelargoniums, Begonias, Gloxinias, &c., the Balsam, a mere tender annual, has found formidable competitors, yet none of these plants give just the firm of merit which attaches to the old favourite. None have that tree-like habit of growth in miniature which the Balsam shows; none are so easily raised from seed, and in so short a time none give less trouble; and perhaps it is for some of these reasons that the Balsam is now less grown in gardens than it was many years ago. Happily, whatsoever the nature of appreciation exhibited for the flower, at least it has not entirely staid still in its development. We never had finer or more varied Balsams than we have now, and plants that, if well grown, have sturdier habit and bloom so profusely. The Balsam gradually developed doubleness as well as compact sturdiness from out of single flowers and a loose habit of growth, through semi-double flowers that seem to those who recollect them as poor indeed compared with the splendid double flowers that present good strains produce. Whatsoever may be the taste for single flowers of various kinds as compared with double ones, at least no one ventures to contend that single-flowered Balsams are either meritorious or beautiful. We have them now so double-flowered that it is doubtful whether they can ever be excelled in that respect, especially as for our stocks we must ever be dependent upon seed, and the intensely double flowers are rarely fertile, the seed-pods being generally produced from smaller flowers of the same plants. The forms

CAMELLIA-FLOWERED AND ROSE-FLOWERED as applied to Balsams practically differ only in name. They are intended to indicate one large double character of the flowers of any fine strain, and these certainly do bear close resemblance, if not quite in size, at least in appearance, to good double Camellia blooms, or, as some may think, to Roses. Balsams have three distinctive characters in colours or markings. There are the pure self, the stripes or flakes, and the spots or blotches. Why these spots or blotches should come is a feature which probably can only be determined by a close study of Balsam physiology, but it is not at all a common feature in flowers. Stripes or flakes, on the other hand, are common enough, though, perhaps, in Carnations more than in any other flowers. I might have included an intermediate speckled section of which a variety from France, once known as Solferino, is a good example, but these forms are combinations of the striped and spotted forms after all. None are more beautiful than the selfs, especially the fine whites, carmines, scarlets, crimsons, mauves, violets, &c. Next in beauty are the purple, scarlet, and carmine grounds much spotted with white. The others of striped or speckled forms are pleasing, just as fancy tints may be liked otherwise. Still, a dozen of the best colours and markings give enough to satisfy

anyone, and a good selection is best ensured by purchasing seed in ever such small quantities in separate colours. Usually the continuation of a good variety is maintained by saving seed from the best forms separately, for it is found that Balsams sport very little and generally reproduce their kind with constancy. When Balsams are grown for ordinary greenhouse decoration, there is perhaps less of importance in variety than there is if grown for the production of exhibition plants or for bedding. Not every gardener understands the value of Balsams as bedding plants, and yet in their season, if well done, they are very beautiful. They do not require a soil that is too rich, and they like it to be tolerably firm. If a raised bed be planted, and not too stilly or regularly, there should be a carpet of some dwarf plant, such as a blue Viola, which would afford a good contrasting base to the more bizarre colours of the Balsams. I have found, after many years' experience of growing

BALSAMS OUTDOORS, that it was better to dibble the plants out, so as to somewhat, at the first, restrict the roots, than to first pot them singly, and to turn them out from the pots into the ground with all their roots in full activity. Plants so treated, and especially in rather fine loose soil that was manured, would develop excessive growth, especially of side-shoots, and, in fact, do anything but bloom well, hiding what flowers were produced in an excess of leafage. When that form of growth happens it is well to lift the plants from the soil with a fork, so as to check root-action and to replant again at the same time, severely thinning the side shoots. But it is better still to prevent that growth by transplanting direct from the seed-pans, the plants being first well seasoned by exposure, into the open ground, and when bloom begins there is little fear of too much short growth resulting. In any case, a little pinching or thinning will seen at all right. I have often found much reason to admire the exceeding beauty of a fine mixed strain of Balsams so grown, and have wondered that they have not been widely utilised for bedding. Even if only dibbled out singly or in trebles into ordinary mixed plant borders, they are beautiful also. Balsams are in their early or seedling stages very much injured by being kept in close places, and are thus drawn out of natural form just when ample light and air are so essential to the production of a stout, sturdy childhood. From the moment the plants are 2 inches in height they need ample light, and should also be kept as near to the glass, whether in a house or frame, as is possible. When pricked off singly into pots, as of course they must be if intended for pot culture, the stems should always be kept somewhat hurried in the cell, and that has to be done at every fresh potting, for not only does it tend to keep the plants dwarfed, but the stems emit roots which help also to sustain the plants in their later growth. Balsams do not require excessive pot-room, and the best of plants, of good height and breadth, and in profuse bloom, may finally be had from pots not more than 8 inches across the top. When the soil is of the right sort—a mixture of three-fourths

STRONG TURFY LOAM and the rest of cow-

manure and leaf-soil—it is surprising how it will sustain the plants, and being gross feeders, they can, when fully rooted, be well sustained by frequent waterings of liquid-manure. I have found a couple of bushels of clean horse-droppings put into a coarse bag and placed in a tub containing twenty gallons of water to furnish capital liquid-manure for Balsams, and it is of a kind that can be oft repeated when the first bagful of manure is exhausted. A little eot may also be advantageously mixed with the liquid. Really good exhibition Balsams should be about 30 inches in height and 24 inches through, each plant carrying a dozen at least of stout branches all covered with large double flowers and good leafage. Such plants are not temporarily beautiful. They give at least from eight to ten weeks of beauty, and that is not at all a bad product for tender annuals whose ordinary lives rarely exceed six months. A.

A note on Gallardias.—The Gallardia is one of the more important plants in flower during the late summer and autumn months. It succeeds best in a light soil, and produces flowers with great freedom. One wishes that there was a little greater variety in the colouring, the colour varying from crimson to self yellow, such as Vivian Grey. The plants like a warm, fairly light soil, and under such conditions they will continue to bloom over a long season, whilst the flowers are very useful for cutting. I notice that they are being grown not only in both small and large gardens, but also in the parks of London and other cities. It is not difficult to raise them from seed, and if the seed is sown at once, plants will be obtained in autumn, which will about one year old bloom freely. Sow the seed in the open, selecting not too open a spot, but where the ground is well prepared and moderately rich. Amongst the seedlings there will be naturally many inferior things which may be weeded out, retaining only those of fine colour. The two principal colours are crimson and yellow, usually associated in the flowers, edged with the latter tone, this varying greatly in depth. I have lately seen, however, departures, getting into more of rosy tint, so that in time the range of colouring will be extended. Get good seed, and then you may rest assured that the "strain," as it is called, will not be disappointing. The plants suffer in winter if not in a well drained soil, but by having a good stock of seedlings a supply is always on hand. A popular name for the Gallardias is Blanket-flower, not inappropriate, by reason of the woolly nature of the gay-coloured blooms.—V. O.

4431. — *Lilium auratum*. — Without knowing the condition the flower-stems were in when they were cut down I cannot say positively whether it was wrong to cut them down or not so early in the season. This much I may, however, say, that the stems should be allowed to die down before they are removed. If those you have had the stems cut down when they were green, you may depend upon it the bulbs have been weakened by it. Under any circumstances the proper treatment is right, so that if they fail it will not be your fault.—J. C. C.

GARDEN WORK*

Conservatory.

Mignonette may be sown any time during this month for blooming after Christmas. Make the soil very firm, and use good loam, mixed with a little old manure. See that the drainage is free. One of the chief factors of Mignonette growing is good light, made sure by raising it high with the pots. On this head, the seeds are sown thinly. Place the seed-pots in cold frame and keep just moist. Thin the young plants to about four or five in a pot, leaving, of course, the best. It is now time to check the growth of Salvia, Eupatoriums, and other plants turned out to make growth, with the view to lifting in September, towards the end of the month, or earlier if frost is expected. The check is best given by cutting the roots round with a spade, so as to leave a well just large enough for a 9-inch pot. Large plants may require larger pots, but it is as well to keep these things in as small pots as can be done conveniently. The early bulbs will now be making some progress in root formation. Let them remain plunged outside till the pots are well filled, and then there will not be much trouble. The general collection of forcing bulbs, Hyacinths, early Tulips, and Narcissus of various kinds should be got home as soon as possible. Single Hyacinths are best for growing in water, and they are also best for forcing in pots. The best result is obtained when the bulbs are potted early and allowed to remain in water till the time of flowering is given. Cinerarias, Primulas, Cyclamens, and other plants usually flowered in moderate-sized pots should have a shift before the plants get pot-bound. We grow a good many of these in 5-inch pots, but, of course, 6-inch pots are not large enough for good-sized specimens. Plants for forcing may be shortly potted up. We usually strike cuttings early from forced plants in heat, pot off, and plant out. When established the best of these, to the required number, are lifted and potted up towards the end of September. Mrs. Sinkin is one of the best varieties for this work. Hard-wooded plants must be placed under cover before the autumn rains set in. They are all right so long as the weather continues warm, but, exposed to a sharp autumn frost, the flower-buds will probably suffer. If there are any signs of thrips on Azalea rest them cleaned at once by syringing or dipping. Azalea Mollis and Deutzia gracilis must be potted up shortly for forcing. Cactuses in cold pits or frames must be well exposed to ripen the growth. Gradually reduce the water now, so as to get the growth well matured, and there will be a harvest of flowers in due time. Continue to reduce diluting plants as anything goes out of flower, and encourage growth in Fibreal Tropaeolums and any other plants which has any effectiveness in the winter.

Unheated Houses.

At the present time this house is gay with Tuberosus Begonias, Fuchsias, and Lilies of various kinds, all of which may be kept through the winter in a resting and dormant state without artificial heat. The pots will be plunged in Cocoon-fibre, or before frost set in paper covers specially prepared will be placed over them. For winter decoration there are bushes of Laurustinus, Andromeda floribunda, Jasminum nudiflorum, nice little bushes, and Gold and Silver Broomynus, and several berry-bearing plants, including Perpetua speciosa.

Ferns under Glass.

Use as little shade as possible now. All permanent shading, such as whitewash, &c., should be washed off; strong soda ash or potash will be placed over them. For winter decoration there are bushes of Laurustinus, Andromeda floribunda, Jasminum nudiflorum, nice little bushes, and Gold and Silver Broomynus, and several berry-bearing plants, including Perpetua speciosa.

The North House

can be cleared now for the Aralae and hard-wooded plants generally. Up to the present this house has been most useful in keeping flowering subjects back, but the brilliant sunshine made even north houses better than usual. Lappagerias, both the white and red varieties, do well in the north house. Make a good border of rough peat, with a few rough pieces of old tarry loam mixed therewith, the border to be well drained with broken bricks, and should be at least 2 feet deep. The Lappagerias may be trained up the wall and then under the roof. It would be a pretty sight to see a house well furnished with Lappagerias, and the flowers would be valuable.

Stove.

Assuming that the house has been thoroughly cleaned with soap and water, the woodwork should be painted if necessary. These houses are not painted often enough inside. Drops from a roof in bad condition often damage a tender plant, and, besides, a coat of paint is one of the best aids to the getting rid of insects, especially that pest, mealy-bug. Shade will not be required now, and trees must be kept going regularly. After the house has been cleaned, the plants which have been moved in either house for the summer must be brought back, some of which must be thrown away. It is a great struggle sometimes to throw out old favourites, but plant growers must not indulge in sentiment. There are young plants coming on which must have room, and so the old plants must either be thrown away or otherwise disposed of.

Frame Culture.

Late Melons will require new linings to help the bottom heat, and warm coverings will be required at night. The plants in frames are not making so much growth now, and there will be less scope for pinching and pruning. Cucumbers in frames may be carried on till the end of October by the aid of warm night covers and linings of warm manure round the frames. Give all the air possible at night in Cinerarias, Primulas, and Cactaceae. The

* In cold or northern districts the operations referred to under "Garden Work" may be done from a fortnight later than those indicated with equally good results.

night dews refresh the foliage, and they get sturdy and robust. Of course, frost must be guarded against. Several frames will be full of cuttings now, and as soon as the cuttings are rooted air must be given freely, and if at all crowded the pots must be opened out.

Chrysanthemums

must be opened out a bit. This can be done by taking a plant here and there out of the line and open the obverse out. It means a little more work, but a little of the kind is beneficial, and permits the air to circulate all round them. When the plants are crammed closely together the leaves are not properly developed and hardened. The buds have not been all selected, and, as the pots are full of roots, liquid stimulants must be given three times a week.

Window Gardening.

Fern cases will still require plenty of water. Dead fronds must be picked out; the faded leaves will soon be replaced with new growth. Cuttings of plants rooted outside should now be potted up and stood in the shade to get established. Asaleas, Camellias, and hard-wooded plants generally must soon be placed indoors, in a cool light room, and watered with care.

Outdoor Garden.

Seeds of many flowering plants are ripe or ripening, and anything good should be sown. Good Hollyhocks are always worth saving seeds from. Cereations will ripen seeds in the open air this season; at least, I am watching a number of plump pods on open air plants. Of course, it is no use saving seeds from any but the very best. Cereas will ripen more seeds than usual this year, and other good things are worth looking after. It is late for layering Carnations, but any plants which have not been layered should have attention in the principle of better late than never. Rose bedding is about on a par with Carnation layering. Any trials that were not in condition earlier may be budded with every chance of success now, but do not shorten the shoots. Keep the buds dormant during the autumn and they will break strongly in the spring, and make fine heads. Grass and weeds have made rapid growth lately, and have in well kept gardens involved a good deal of work. Weedy walks are best dressed with weed killers. When dressing a walk, dry hot weather the weeds die and disappear. Dahlia will require a good deal of attention in destroying earwigs, which are very numerous this season. The growth has been rapid lately. Thinning and tying must not be neglected. Where alterations are contemplated the work may soon begin now. Workmen will get through more work now than in the short days in winter. New lawns may be laid and evergreen shrubs transplanted in September. New lawns may be sowed down now if economy is an object. Good turf is best if the lawn is required for immediate use, but the expense is more. Evergreen and other hedges may be got over again now with the shears to make them ready for the winter.

Fruit Garden.

Vines in pots intended for forcing next year will now be approaching a condition of maturity. The finishing touch may be given out to the side against a south wall. At no time should the vines be kept in pots, but, if permitted to get dust dry. A plant in a pot soon gets dry. I suppose, nowadays, no one grows pot-vines without the use of artificiality. I can strongly recommend the Patent Silicate Manure either for mixing with the soil in which the plants are potted or as a top-dressing. It is cheap enough to use freely. I know nothing about its constituents, but it does not produce rank growth, its tendency being in the way of firm growth and abundant fruit-bearing. I have used it for two seasons, chiefly upon Vines and Peaches, and most assuredly I should not purchase anything unless I was satisfied with it. In making new plantations of Strawberry, except if may be for purposes of experiment, rely chiefly upon well bred sorts. It will be a long time before we lose sight of Sir J. Paxton and President James Vetch bears very fine fruit. British Queen ought not to be recommended for general planting irrespective of soil and climate, but grown in a good deep soil and a genial climate, and there is no Strawberry pays better. Let me advise all who are planting Strawberries upon dry, porous soil to be in the habit of manuring a good deal of peat, say one peat to the square yard, of common soil—be worked into the land during the last fork over. Apples and Peas are putting on colour, and the late rains have given size, but then comes the complaint that good Apples are worth nothing, that there is no sale for them at all. I feel sure these complaints come from people who have not mastered the details of marketing. That Apples will be cheap this year goes without saying, but prime samples, carefully packed, will pay in local markets, I feel convinced.

Vegetable Garden.

Weeds are giving trouble, and must be hoed up when the sun shines and got rid of. The earth stirring will be beneficial to all growing crops. All late summer and autumn seed sowing has been a marked contrast to the spring and summer seed sowing. Seed sowing, since the change came in the weather, has grown remarkably, and the young plants will need timely thinning. It will be of no use to sow Turnips now except for the purpose of spring greens, and it hardly pays to sow for that purpose. Get the land from which the spring sown Onions have been cleared prepared for Cabbages. It is not generally necessary to dig deeply or manure heavily, as the ground is usually well done for Onions; all we do is to give a sprinkling of soot and fill it in lightly, then draw drills 12 inches apart, and set out the plants in the drills, giving a good soak of water as soon as the plants are finished. Cucumbers for autumn and winter forcing may be planted any time now. Every part of the house must be thoroughly cleaned before the plants are set out. Only strong plants should be employed. If strong plants of a free-setting variety of Tomato are set out now in a well heated light house a crop may be gathered in winter. The plants may then be shortened back, and a heavy crop gathered from the new wood in May, June, and July. They must have liberal treatment right through. A good form of the Old Red requires some beating for winter work—it acts so freely. Chill French Beans in winter, which can be heated to a temperature of 60 degrees for winter bearing, or they may be sown in pots and brought on in Pine or other forcing houses.

Work in the Town Garden.

This has been a grand season for Grapes in unheated vinerias and greenhouses, and in the open air also. I could mention several cases in which excellent crops of Grapes have been produced in totally unheated structures, under decidedly rough and ready treatment, and the fruit is now nearly or quite ripe. To my mind Grapes, especially when of the Black Hamburgh or other good old fashioned varieties, thus grown in a cool and well-ventilated house, are infinitely superior to the huge overfed Gros Colmar and others now so generally seen in shops, &c., and which are in many respects better than those for a Vine are now almost entirely devoid of both substance and flavour. While the fruit is colouring the Vines cannot have too much of either air or sun, and care must be taken to remove all late or secondary growths with the finger and thumb, either pinching them out altogether, or if the foliage is at all scanty, stepping them beyond the first perfect leaf. There are few better climbers for the roof of a town greenhouse than a Vinn, and if the growth is not too thick the shade will be beneficial rather than otherwise to any pot-plants beneath, during the summer time, but these last have to be splendidly seen in the open air, for a Vinn are now so full of other things do not agree at all. Tomatoes carrying heavy crops of fruit must have abundance of moisture and liquid manure at the root during such weather as we have experienced lately. If the border is properly drained and not too deep, and the soil thoroughly porous and sweet—a sandy nature preferably—it is scarcely possible to overwater these plants under present circumstances, by fair means at least. Plants in pots, now full of roots, will require watering twice or possibly thrice daily. This has so far been splendidly seen in the open air, for a Vinn are now so full of other things do not agree at all. Tomatoes carrying heavy crops of fruit must have abundance of moisture and liquid manure at the root during such weather as we have experienced lately. Tomatoes carrying heavy crops of fruit must have abundance of moisture and liquid manure at the root during such weather as we have experienced lately. If the border is properly drained and not too deep, and the soil thoroughly porous and sweet—a sandy nature preferably—it is scarcely possible to overwater these plants under present circumstances, by fair means at least. Plants in pots, now full of roots, will require watering twice or possibly thrice daily. This has so far been splendidly seen in the open air, for a Vinn are now so full of other things do not agree at all. OUTDOOR PLANTS.

PLANTING CARNATIONS.

All who love and grow Carnations should make a point of resping as far as possible some of the advantages that the present season offers. The good of it, so far as Carnations are concerned, will go beyond the year, materially helping us through the winter, and ensuring, as far as our own efforts can, a good display for another year. Never before have I been able to begin planting in August with layers put down the same season; but this year planting was commenced during the middle of August. It was not a hasty attempt to plant a few to make a record, but a fair beginning with layers having halls of roots as large as one's fist. Planting has continued ever since, and there is every prospect of its being completed by the average usual date at which it commences. With everything so early, and layering performed a month in advance of the ordinary time, early planting followed, or should do so. My point is, that as soon as the layers are really fit for removal plant them, if possible, where they are to bloom. Six weeks from the date of layering is ample time to allow for rooting, and then the all-important thing is to get them up and put out in their flowering quarters. My advice, therefore, to all amateurs is to begin and finish as soon as you can, and then the plants will obtain such a root-hold as to be firmly anchored in the soil and able to resist all the upheaving tendencies of the frost's action. A few words as to soil. There is nothing like loam, but in a fresh state it is very much beset with the most mischievous of pests, wireworm. Ordinary garden soil will grow good Carnations. I have just planted out nearly three dozen layers of

COUNTRESS OF PARIS CARNATIONS, and they were all taken from one plant, which was grown in the soil of a vegetable garden that has been in cultivation many years. In planting I adopt a plan that I have long since proved to be beneficial to Carnations, and no doubt it in some measure helps to circumvent enemies. When the hole is dug out and the plant put in, a handful of some mixture of sand and fresh soil, with soot, wood-ashes, or any ashes from burnt refuse, is put upon the roots and around the stem. Before filling up, too, the plants are carefully watered in. In the present dry condition of the ground it would be fatal to many plants if they were not watered in. Morn surface-watering after planting, &c., is completed is altogether insufficient to reach the roots, and beneath the tropical sun that was shining during the early days of present planting, without abundant moisture at the roots, death would soon result. Another advantage of this form of thorough watering is that it is usually enough to carry the plant through till fresh rooting takes place. Amateur friends need not despair if loam is unobtainable. Dig up the ordinary soil to a good depth. If it needs manure, let that which is added be thoroughly decayed, and use soot or wood-ashes as well. Then plant early, see that they are well moistened at the root, and last, but far from least, make them firm in the ground. It is attention to and the perfect carrying out of these apparently small, but all the same most important, details that contribute so much to ultimate success. A. H.

4413.—**Nettles on a farm.**—Nettles do not usually thrive on well-cultivated ground. The roots should be gathered as the land is ploughed or harrowed. Many roots will escape, and good crops of Nettles may appear above ground next year. As soon as they do so cut them down with the hoe. They may grow again, but should be persistently hoed down as they appear. They will die out the first year if they are not allowed to make any growth above ground. They may be exterminated from pasture land in the same way. Cut them down constantly with a scythe or hook.—J. D. E.

—Keep them constantly cut down through the summer, and the roots will die for want of access to the air. It is only a question of sticking to it for a year or two. A good lad would manage it.—E. H.

4428.—**Sowing annuals.**—All the annuals named, except Marigolds and Chrysanthemum vegetum, may be sown now, though it is full late enough. Old seed-bed plants are getting quite strong.—E. H.

WHITE HAIRBELLS.

Amongst the Hairbells there are several with flowers of exquisite delicacy and spotless purity of colour, such as the variety of *C. isophylla*. This is a Campanula all should grow who love white flowers, and another that should not be passed by is the one here illustrated and known everywhere as the White Peach-leaved Hairbell, a lovely flower, invaluable for giving beauty to the garden, and most useful when out. This may perhaps be accounted the most useful of the group to which it belongs, and is entitled to a place on every border, worthy of the name, though there are many gardens from which it is absent. The double form of this has many uses, as the flowers are resette-like, and when mounted neatly on wires might be taken for small blooms of the fragrant *Gardenia*. A very good use to make of this Campanula, but one to which it is not often put, is to grow in pots, and if properly cared for, flowers may be obtained in spring if the plants are given a judicious amount of heat. At that season the flowers will have an additional freshness and beauty by reason of their tender grace and purity. Both the single and double-flowered forms are of free growth, and an easy way to propagate is by division of the roots in winter, and here I may offer a few remarks respecting

White Peach-leaved Hairbell (*Campanula persicifolia alba*.)

the culture. Neither the type nor its numerous forms present any great difficulties in this respect. One of the common faults, and most noticeable when many gardens are visited in the course of the summer, is that the plants are not divided frequently enough. When it is seen that they are becoming weakened, either through the poverty of the soil or enervated growth, we lift the plants carefully, divide them, and plant in other positions that have undergone some preparation. The tufts will then grow away with vigour, and a free display of flowers will soon follow. The best time to divide is the winter, but it may be done in the early spring without harm. Whichever term is selected, plant quickly, so that the roots are not unnecessarily exposed to the atmosphere. It is well also to remove

DECAYING FLOWER-STEMS, as by prompt attention in this respect a few blooms will appear throughout the summer and early autumn, and the strength of the plants will not be unduly taxed. Besides the above varieties there are several others that deserve recognition, and amongst them is the variety *alba coronata*, a semi-double flower, pure-white, with the outer row of petals forming a kind of frill to the bloom that renders it at once distinct and desirable. Then we have a fine variety sometimes catalogued simply as *C. persicifolia coronata*, and again as *C. p. coronata*

corulca, these having blue flowers that present a good contrast with those of its near relative. There is also a double form of this blue variety, which, if a select group of the *persicifolia* type is desired, should find a place. Another that is entitled to consideration is *P. persicifolia maxima*, which, as conveyed by the varietal name, is distinguished by its large flowers. A group of this interesting type of Campanulas would make a most interesting feature in the hardy garden. The Campanulas, though their merits are widely known, are not cultivated to the same extent as one might suppose from their sterling usefulness, great beauty, and diversity of habit. We might have many of the Hairbells in a garden without producing same. Some are most at home on the rockery, either on a jutting ledge that they can scramble over, or in a snug, warm chink or recess. Others, like the *persicifolia* group, display their characteristics to most advantage on the herbaceous border, where with other homely plants they give naturalness and great beauty to the garden during the summer months. B.

4362.—**Herbaceous plants.**—There is perhaps a little confusion in some minds as to what constitutes the term "herbaceous." But I have always been accustomed to take the broadest possible views on this subject, and should include almost everything which had a perennial character whose growth died down every year. There are, of course, evergreen and deciduous herbaceous plants, and if one was at all fussy, a distinction might be made between those which disappear under the ground in winter and overgrow; but for all practical purposes one class might contain the whole. The following list contains both: *Achillea Ptarmica plena* (July and August), *Adonis vernalis* (March), *Alstromeria aurantiaca* (July and August), *Alyssum saxatile compactum* (March), *Achuaa italica* (June and July), *Anemone spinnina* (April), *A. fulgea* (March), *A. japonica*, *A. j. alba* (August to October), *Anthericum lilasrum major* (May and June), *Columbines*, *Aquilegia chrysantha*, *A. glandulosa* (May and June), *Arabis alba* (March), *Armeria cephalotes* (Giant Thrift) (June), *Asperula odorata* (Woodruff) (May), *Asphodelus albus* (April and May), *Asters* (*Michaelmas Daisies*), *A. bessarabicus*, *A. dumosa*, *A. uricoides*, *A. lewis*, *A. turbinellus*, *A. Nova Angliæ*, &c., *Auhretia Hendersoni* (March), *Bocconia cordata* (Tree-Celandine) (July), *Buphthalmum salicifolium* (May to July), *Campanula carpatica*, *C. o. alba*, *C. grandiflora* Marisol, *C. grandis*, *C. latifolia alba*, *C. nobilis*, *C. n. alba*, *C. persicifolia* fl. p. *C. p. alba major*, *C. p. alba plena*, *C. turbinata*, *C. Van Houtte*, *Catananthe bicolor* (July to August), *Centaurea macrocephala* (July), *C. montana* (May to August), *Chrysanthemum latifolium*, *C. semiduplex*, *Coreopsis grandiflora* (June to September), *Delphinium in variety* (June), *Dicotyles Fraxinella*, *D. F. alba* (June to August), *Dielytra spotochilla* (April to May), *Doronicum plantagineum excelsum* (April), *Echinops ruthenicus* (July to August), *Eryngium amethystinum* (July), *Funkia subcordata grandiflora* (September), *Gaillardia grandiflora* (June to September), *Galga officinalis compacta* (May to July), *Geranium armenum*, *G. cinereum*, *O. lancastrense*, *G. sanguinum*, *G. sylvaticum plenum* (May to August), *Genm areum*, *G. coccineum grandiflorum* (May to July), *Gladiolus The Bride*, *G. Marin Lemoine*, *Cypripedium panicula*, *Helenium pumilum*, *H. autumnale* (June to August), *Helianthus rigidus*, *H. decapetalus* (August and September), *Heperis matronalis alba-plena*, *Double White Rocket* (June and July), *Helleborus niger*, *H. angustifolius*, *Hemerocallis flava* (Yellow Day Lily) (May and June), *Iberis corisifolia* (May), *Inula grandiflora* (June and July), *Iris German* and others, *Lathyrus* (Everlasting Pea, white and red) (June to August), *Liatris spicata* (June), *Liliums in variety*, *Lupinus polyphylla*, white and blue (June to August), *Lychnis chalcidonica* fl. plena, *Lythrum roseum* (June to August), *Mulva moschato alba* (July to September), *Montbretia crocosmioides* (July to September), *Geothera frutescens majus* (June to August), *Pionias in variety*, *Poppies in variety*, including *Island* (nudaule) *Orientalis*, and *bracteatum* (June to September), *Phlox in variety*, *early and late*, *Polygonum com-*

patum, *P. cuspidatum* (July to September), *Primula rosea* and many others in shady borders, Pyrethrum in variety, including *niligiosum*, the large single white, flowering in autumn, *Ranunculus aconitifolia plenna* (Fair Maids of France) (May), *Rodbeckia Nowmani*, *R. purpurea* (July to October), *Senecio pulcher* (July to October), *Silene grandiflora* (May to July), *Spiraea erucica* (June and July), *S. Filipendula plena*, *S. venusta* (June to August); *Statice latifolia* (Sea Lavender) (July to September), *Trollius europaeus* (Globe-flower) (April to June), *Tritoma grandis* (Torch-flower) (July to October), *Veronica Hendersoni* (July), *V. Traversi*, *Pinke* in variety, *Carnations*, &c. This list might be extended, but all the above are good and afford a wide range of season and colour.—E. H.

4425.—**Begonias in the garden.**—Both the double and single varieties thrive remarkably well when planted out in the open ground, though the intense heat of last week scorched up a lot of mine where not shaded; but the large, full blossoms of the former are so exhausting to the plants that they cannot be expected to continue in flower as long as the singles. Give them plenty of very old manure or spent Hops, and a little good stimulating fertiliser, such as Thomson's, or good guano when the first flowers are getting over.—B. C. R.

—The Double-flowered Begonias, from my experience, are far better in pots than the open ground, and the reason is obvious. They require more individual treatment than they get in the open, where also the flowers, usually very heavy, although of brilliant and diversified colours, are battered about with storms of winds and rains. You must remember that the finest strains have very large flowers, and it is not to be expected that the same freedom will be shown as in the single kind. I should next year try and get some of the semi-double race, which I have noticed this season succeeding remarkably well in the open ground. These, I think, will become the double Begonias of the future. The flowers not so large and heavy as in the ordinary double kinds familiar to you, but more what florists call duplex, the centre being quite like a little rosette and the outer segments form a kind of foil to this mass of florets. But the charm of this race is that the flowers are produced very freely, and held well up so that they toll with force in the gardens. I saw a bed a few days ago which was a mass of colour, but I do not know where the varieties can be obtained. Possibly the nurserymen who deal more especially with Tuberosus Begonias will help you.—C. T.

4407.—**Gladioli from seed.**—The production of Gladioli from seed is one of the most interesting modes of cultivating this handsome autumn flower. Few of these favourite garden plants that have been improved by the skill of the gardener is so easily managed. The seed should, of course, be sown from the cross-fertilised flowers, selecting only those of good form and distinct colour as seed and pollen-bearers. The seed does not take very long to ripen, and the pods should be gathered as soon as they burst open. Lay them out to dry and label each cross with the names of both parents. My plan is to sow the seed thinly in 6-inch and 7-inch flower-pots. About the first week in April plunge the pots in a hot-bed. In a week or ten days the plants will appear. They are left in the frame just as they are, the heat gradually declines, and air is admitted freely, so that the plants may make healthy good growth. By the end of May remove the lights altogether. Attend to them with water, and by the end of September each plant will have formed a bulb. Dry them off, and in October pick the bulbs carefully out of the soil, and keep them in a dry frost proof place in a little sand until the first of March, when they may be planted out in rows 18 inches asunder and allow a space of about 6 inches between each bulb. Although the bulbs may not be larger than Peas, most of them will give a good flower-spike in August.—J. D. E.

—The raising of Gladioli from seed is not a very trying mode of propagation, and the chief joy in thus raising from seed is the anticipation of novelties, new shades of colour, something distinct from any that have previously appeared. If you have already a collection of Gladioli in bloom, the flowers must be artificially fertilised, and I select only the best from my temple to

anthers with the finger to prevent the pollen escaping, otherwise the crowns will be interferred with. The time to pick the seed-pods is when they commence to open at the top. Save the seed carefully and it will germinate successfully in the early ripening months, if sown thinly as in the usual way. Prepare sufficient 48 or 5-inch pots, crock them well, and use moderately light soil. The seeds germinate freely and readily as a rule, and the bulbs should be kept in pots through the summer, being planted out in the following March. They will for the most part bloom the same year, and then the finest for colour, shape, and other points should be selected. The soil for Gladioli should be fairly rich and deep.—C. T.

—How the seeds in boxes in a slightly heated frame in February, or in greenhouse. Harden off and prick out 4 inches apart in specially prepared bed as soon as large enough. There is no difficulty in raising Gladioli from seed, and it is what everyone should do who wishes to have a garden well furnished with Gladioli at a small expense.—E. H.

4363.—**Carnation and Picotee seeds.**—August is a very good time to sow these. You had better use a pan or small shallow box, as they can then be looked after much easier than when in the open border. Do not use any manure in the compost; a mixture of leaf-soil, loam, and sand, in about equal proportions, will answer admirably. Cover the seeds a sixteenth part of an inch with the finer portion of your compost, and stand in a cool pit or frame. When large enough to handle prick out into small pots, using the same compost. In the spring they may be turned out into a border, and should flower fairly well during the latter part of next summer.—P. U.

—It is certainly getting late for these now, but I have known plants from seed sown in August to flower the following season; still, you must not lose a day. Sow the seed in a well-drained box or pan of sandy loam or leaf-mould; keep just moist, cover with a sheet of glass, and keep in a frame or greenhouse, shaded from hot sun, until germination takes place. The young plants will appear in much less time under this treatment than if sown in the ordinary way in the open. When little more than an inch high transfer the seedlings singly to thumb-pots, using the same soil, and keep rather close for a time in a frame; when established and growing ventilate freely and give no shade. In October they ought to be strong enough to shift into 3½-inch pots, in which they should be wintered, plunged in ashes in a cold frame or in a cool greenhouse. Any that are not fit to shift should be kept over till the early part of February. Plant them out, having previously hardened them off thoroughly in April, in a bed of good well-drained and well-worked loam of a sandy nature. Most, if not all, of the seedlings will flower during the late summer or autumn.—B. C. R.

—Sow at once in a box or a frame, and prick out in beds as soon as large enough to handle. Most of the seedlings will flower next year under good culture.—E. H.

4371.—**Christmas Roses.**—They will bloom in a London garden at Christmas, but of course one cannot say what the weather may be; there can be no development of flowers during severe frost. They will flower well in the greenhouse with a north-west aspect. The plants should be carefully lifted and potted as the flowers begin to open.—J. D. E.

—Yes, these can be grown and flowered well in the locality mentioned; the aspect also will do, especially if enough artificial heat to rather more than exclude frost can be given. Obtain good strong flowering clumps in October or the beginning of November, and plant them either in boxes or good-sized pots (but preferring the former), using a compost of sandy loam and leaf-mould with good drainage. Keep them moderately moist but not wet, and ventilate freely in mild weather. Some of the clumps may be planted out-of-doors, where in a moderately-sheltered and shady situation they will do fairly well, but the flowers will be neither so clean nor large as those produced indoors, nor will they last so long when cut. The plants inside must be removed to the open air early in May, choosing a lightly-shaded spot, and he kept supplied with water and some weak liquid-manure occasionally as required.—B. C. R.

—Very seldom indeed will Christmas Roses open their blooms by Christmas out-of-doors without any protection whatever, except in the case of an early variety or two—maximus for instance; but then these are not the kinds that are so much appreciated for decoration at that

season. The best way to make certain of blooms of *H. niger* at Christmas is to plant the roots on a border facing east or south, and in such a manner that a frame can be placed over them at the end of October to encourage an early throwing up of the flowers by the aid of a slight heat from the glass covering. It is a mistake to lift the roots for forcing inside, except a large quantity of plants are available, as it requires several years to recuperate these lifted plants before they will flower freely again; but by having them as directed, no interference with the roots is necessary. After the blooms have been gathered and there is no fear of frost injuring the tender leaves remove the frame and feed the plants liberally with liquid-manure, especially if the weather during April and May is hot and dry. It is surprising what a quantity of moisture Christmas Roses enjoy about the roots during summer.—S. P.

4377.—**Clematis attacked by mildew.**—The extreme drought of the present year is the cause of the Clematis being attacked by mildew. Nearly all the plants that I have come across growing in a southern aspect are affected in the same way. To grow Clematis really well, and especially Jackmani, there must be no lack of moisture about the roots, especially just at the time when the buds are swelling and the first blooms expanding. The present attack of mildew will not interfere with the plants in the future, providing they obtain more moisture at the root in the case of a long period of drought. However, a thorough soaking of the soil at once will assist to mature the growth thoroughly.—S. P.

—In all probability this proceeds from dryness at the root or the plants are otherwise impoverished. Treat them well by copious waterings and a mulch of manure or any material that will conserve the moisture will help, and possibly they may make more growth that will be clean and free from the pest.—A. H.

4381.—**Clematis dying.**—It is very provoking to see an apparently healthy plant die so suddenly; but yours is not an isolated case, as I have seen several similar instances. The explanation appears to be that as the better forms of Clematis are grafted upon a common variety the stock suddenly gives out. With regard to what you are to do in the future, I can only advise you to get the plants raised from cuttings if you can; but I am afraid you will have difficulty in doing so, as nurserymen find it easier to raise a stock from grafts.—J. C. C.

4434.—**Water Lilies.**—In all probability the cause of the Lilies failing to flower satisfactorily is overcrowding and exhaustion of the soil. When the tank was emptied and the roots divided it would have been well to totally or partially renew the soil; but as apparently this was not done, it will have to be done before the plants again flower satisfactorily. The tank not being very large, and presumably under perfect control, there should not be much difficulty in doing this. No indication is given as to depth of soil, but probably it is not very great. After the operation has been completed, in the future it would be well to add to the soil from time to time. When the root-run is confined manure is often beneficial, and none is better than cow-manure if it can be procured. I have heard that manure-water added to the water in which the plants are growing does good, but have never given it, all my plants having a good root-run in the natural mud deposit of the lake in which they grow.—A. H.

4411.—**Stonecrop for a rockery.**—This is a very large family, and contains a great variety of suitable kinds for the embellishment of the rockery. The following is a list of twelve sorts, neither expensive nor difficult to cultivate: *Acre aurea elegans* (golden), *Lyidium* (green, very dense growth), *glaucom*, *moerstroem*, *alston*, *albidum*, *oppositifolium*, *laciniatum*, *pulchellum*, *rupestris*, *Sieboldi*, and *stoloniferum*.—B. P.

4380.—**Beet Self Carnations.**—Mr. Martin R. Smith, of Hayes, has given very careful attention to the raising of border Carnations of self colours, with pods that do not burst, and a few of them can be obtained at a cheap rate this autumn. They are Abigail (carmine-rose), Aline Newman (deep-red), Lady Gwendoline (deep-rose), Mrs. Lonisa Jameson (deep rosy-red), Niphotos (pure white). A few of the older varieties are Germania (yellow), King of Soarlets, Midas (pale-rose), Mrs. Reynolds Hole (apricot), Ruby (bright-rose), King of Crimsons, and Oriflamma. The above twelve varieties have been proved in the open borders and have given much satisfaction.—J. D. E.

INDOOR PLANTS,

ERICA VENTRICOSA.

We have at various times dealt with *Erica* in GARDENING, but the accompanying illustration refers to a species which is more grown than any other, and largely represented at exhibitions even in our own day; of course, many stove and greenhouse plants are very little grown now comparatively to what they were a few years ago, when they constituted the pride of the exhibitions. But through times of adversity *E. ventricosa* has held its own, and a more charming pot plant for the greenhouse or conservatory it would be difficult to find. The illustration shows its freedom and usefulness when grown well. There are several varieties: *E. V. Bothwelliana* has flesh-coloured flowers, passing to red, *E. v. coccinea minor* (pink, deep-red at the apex, a compact habitated plant, profuse and showy), *E. v. grandiflora* (rose-crimson), and *E. v. magnifica* (crimson). The culture of the *Erica*, it must be remembered, demands patience and the most careful culture. Few things are so apt to suffer from neglect as the Heath, and the rock over which the amateur usually tumbles is the watering. If once a Heath gets dry it is next to impossible to bring it once

again into a really healthy condition. Those who wish to grow a collection of *Ericas* will find ample information in recent issues of GARDENING, and if a selection is made *E. ventricosa* and its varieties should be included.

gatum is a beautiful trailing plant, with very distinct variegation, and one of the most beautiful of all variegated plants. *Tradescantia zebrina* and *elegans* are respectively dark and light variegated-leaved trailing plants, and of the easiest culture; half-a-dozen cuttings put into a 3 inch pot soon develop into beautiful pots full of ornamental foliage. *Thunbergia alata* and *aurantiaca* are very pretty trailing plants that are raised from seed. The flowers are very freely produced and distinct. These plants are not nearly so much grown as they deserve to be. J. G., Gosport.

The Streptocarpuses.—These are plants suitable for amateurs. They are not hardy, but may be grown with little artificial heat, and represent a comparatively new race that will become in the future as popular as the well known *Gloxinia*, which is far more difficult to grow. The seed should be sown thinly, and just sprinkled over with soil. Use a shallow pan or pot for seed raising. The seedlings will bloom in about six months from the time of sowing, and from a packet of seed will be obtained a great variety of colours varying from white to the richest crimson, more or less blotched on the lower segments. One may compare the flower to that of the *Gloxinia* as regards

a compost of sandy loam and a little thoroughly decayed vegetable refuse. One great point is to have a little pure coal-rot at the bottom of the pot, just over the drainage. This last should not be so hollow as is generally the case or the roots are apt to come out through the bottom of the pot, and as they resent any interference this must be avoided as much as possible. Sow the seed in the pot, never attempting to transplant. I do not know of any annual more impatient of transplantation than the *Mignonette*.—P. U.

4427.—**Sulphur in a greenhouse.**—I am afraid that coating the flue with either cement or mortar will not prevent the escape of the fumes into the house, as both these materials are liable to crack when so used. It is, however, worth a trial to use cement, but it must be put on $\frac{1}{2}$ inch thick, and the sides of the flue must be well wetted immediately before the material is used. The cement should be mixed with water to the consistency of ordinary mortar, mixing up a little at a time and laid on directly.—J. C. C.

—You should have the flue thoroughly overhauled, raking out an inch or so of the old mortar from between the bricks, and repointing the whole very carefully, as well as filling up any cracks or faults, with a mixture of the best lime mortar, with a small quantity of Portland cement. Cement alone will crack with the heat. Possibly the draught also is faulty. If so, have the chimney and flue itself thoroughly swept, and if there is a damper at foot of chimney, have it removed and placed just above the fire; or, better still, regulate the draught by means of an air-tight door to the ash-pit. A damper at the foot of a chimney throws the fumes right into the house when even partially closed. This is just where it ought not to be placed.—B. C. R.

4421.—**Fuchsias.**—The plants might be cut down, but not now; wait until the spring, then see that the soil is nearly dry, cut them down to 6 inches of stem, place them in heat, and syringe frequently overhead. When the young shoots are 2 inches long, shake the plants out, reduce the roots, and repot in smaller sizes, shifting them on again as required. I should, however, advise you to take a batch of cuttings from the plants early next month (September), and then if the old plants fail to do well you will have the young ones to fall back upon, and in any case these will probably be found more vigorous and useful than the others.—B. C. R.

—Six-year-old *Fuchsias*, unless they are planted out in a conservatory border, are not so effective as younger plants. Put in cuttings now. Get up a stock of young plants and keep them growing through the winter, so as to have strong plants to start with in spring. The old plants may then be planted out in the borders, where they will make a good display, and if the crowns are protected with mounds of ashes at the approach of frost they will throw up strong shoots every season and be very effective.—E. H.

4391.—**Eucalyptus globulus.**—This is naturally a tall and rapidly growing tree, and if they do well will attain a height of 10 feet or 12 feet in a very few years. You can cut them down, of course, in the spring, March or April is the best time for this; but then you destroy the beautiful pyramidal habit natural to the tree. A few cuttings may be inserted in the greenhouse next month or in October, but it is doubtful if you succeed in striking them. Seedlings make the best plants, and in order to enable them to develop their full beauty they must have liberal treatment and plenty of room.—B. C. R.

4378.—**Neapolitan Violets.**—Do not remove the plants to a frame, it will only weaken them. Let them alone, affording, if possible, a moderately sheltered aspect and good soil. In April next you can plant out the rooted runners from these plants in good soil and an open situation, and with good culture they will make fine clumps for winter flowering in frames the following winter.—B. C. R.

4372.—**Destroying Nettles.**—Nettles are very easily destroyed. If no growth is permitted above ground there will be no Nettles in a couple of years or less. Have tops constantly pulled by a lad when they appear. If allowed to develop a new lease of life is given.—E. H.

4374.—**Manure.**—Yes, the Peat-Moss-litter is excellent for all vegetable crops, and goes twice as far as the ordinary sive-manure. With a fair supply of this, some of the roots of the *Fuchsia* tribe, and a little nitrate of soda for the *Fuchsia* tribe, you should be able to grow anything to perfection.—B. C. R.

Erica ventricosa in flower.

again into a really healthy condition. Those who wish to grow a collection of *Ericas* will find ample information in recent issues of GARDENING, and if a selection is made *E. ventricosa* and its varieties should be included.

EDGING PLANTS FOR STAGES.

The general effect of conservatorias is frequently marred by reason of the front rank, or edging plants, being of too stiff and formal a habit of growth, and as there are no lack of suitable plants of graceful trailing habit, a short list of these, which any body can grow easily, may be serviceable. *Campanulas*, in several varieties of trailing habit, are excellent summer-flowering plants, easily increased by seed or division of the roots. *Isoplepis gracilis*, one of the best of all trailing Grasses, needs plenty of water to keep it moist; easily increased by division. *Lycopodiums*, or Club Mosses, are especially adapted for edging plants; their beautiful verdant green makes a splendid finish to stages. "Geraniums" of the Ivy-leaf, or trailing kinds, make capital edging plants, and they flower splendidly in small pots and allowed to hang down naturally. Musk of several sorts are useful for summer edging plants; the small flowered kinds are the strongest scented, but Harrison's are most effective. *Parthenocaris*

shape, but much smaller, although in time they will get larger by process of hybridisation. I have measured a single example and it was no less than 4 inches across, but this was truly an exception to, at present, a general rule. A great quantity of bloom is thrown up by a single plant, and the range of colours renders the flowers of value for cutting.—C. T.

4369.—**Stephanotis floribunda.**—This plant is usually produced from cuttings, which strike very freely in heat. It is not at all unusual for it to produce seed-pods, which are about the size of a hen's egg, and much about the same form. When the seed is ripe it may be sown, and it generally vegetates freely. I have several young seedling plants now which I am growing up to a flowering size. The pods are not edible. The first seed-pod I saw were in Scotland, in a small hot-house, in the year 1855. I have frequently seen the *Stephanotis* fruiting since that time, and gardeners who have obtained seed-pods have occasionally noted the fact in the gardening papers.—J. D. E.

4361.—**Pot Mignonette.**—There are comparatively few market growers who succeed in producing this sweet-scented flower in good quality. The few make a speciality of it, and do not readily divulge their secret. You may, however, grow it fairly well by using

ORCHIDS.

PHALÆNOPSIS ESMERALDA.

A VERY bright-coloured form of this plant comes from "Edward Jackson," named P. Baysoniana, asking me if it is correctly named, and though this name was given by Reichenbach some five years ago to a plant I never knew that it was so called. The same authority named a plant which was introduced from Coochin China by my friend M. Godefroy-Lebeuf in 1874, and yours appears to me to be identical with it. It comes from the Gulf of Siam, a part of the world from whence, no doubt, many other fine species of plants will come when it is more opened up. The natural air is very moist and hot, but the plants have been very successfully grown with the other species of the same genus. The flower is very beautifully coloured, and is one of twenty-five upon the same spike, and which must look very handsome, the sepals and petals being nearly equal, deep rosy-lilac, the three-lobed lip being of a rich and rare emethyst-purple. This part of the flower varies very much in colour in different plants. Now I am told by "Mr. Jackson" that P. Esmeralda does not lose its leaves in the winter months; this I should attribute to its not having been thoroughly rested, for I have never seen a plant of this variety which did not lose its leaves after the flowering season. I have always found it a difficult task to get it to wake up again after its long rest, but "Mr. Jackson," however, tells me the plan he has adopted in the cultivation of this plant. He says: "It thrives well in the house with other members of the same family, and although not so conspicuous or so showy as many of the larger-flowered kinds, it is really a very handsome and interesting kind, and it affords one much pleasure. I find this plant thrives well in the East Indian-house, and in a hanging-basket best of all, first draining the basket well, using for soil nothing but fresh and living Sphagnum Moss, and during the growing season giving it an abundant supply of water. I always keep it growing, but in a less degree all the winter. At this time of the year much less water is required. The plant should be hung up near to the roof-glass, giving it full exposure to the light; but I find shade is quite necessary to it during the day, so always have the blind ready to run down over it. At this time, one of the worst faults I have found in growing this species is failing to mow Moss about its roots." My readers here have a successful grower's experience with this plant, which I think is sound and practical, especially his last remark.

MATT. BRAMBLE.

ONCIDIUM SPLENDIDUM.

THE question asked by "Jules Raymond," of how long this Orchid has been known in English gardens, is somewhat perplexing, for the first plant that came into English gardens I saw first in the nurseries of Mr. B. S. Williams, at Holloway, some time in the year 1868, and this was purchased by Mr. Sam Mendel, of Manchester, then an ardent collector of plants; but at his sale it passed into the hands of Lord Londeshorough, at Norbiton, then under the care of my old friend and acquaintance, Mr. Denning, who showed it in flower before the Royal Horticultural Society in the month of February, 1871. Some time after this Mr. Sander, of St. Albans, was lucky enough to get a splendid batch from a collector, and this *Oncidium* became common, and it has proved to be a very free grower and bloomer. I imagine that the reason that my friend "J. R." says his plant does not root freely nor grow well is to be ascribed to the application of too much water. I imagine either he has given the plant too great a supply and not seen that the drainage was of an exemplary character, or he has starved it by giving too little water, and during such hot weather as we have been experiencing the plant has suffered. Now, one cannot expect that this Orchid that has a large amount of moisture to keep built up in its large and thick leaves, can grow and look well if it does not make any roots, and there is another thing about water. What kind of this element do you use for these plants? I was much struck a little time back upon going into a gentleman's Cattleya-house to see the whole

plants looking miserable and bad. I spoke to him about it, and while lamenting it, said he put it down to the very hot weather; but this I could not take for an excuse, and he said that not only did the sun burn up the Sphagnum upon the soil, but it actually burns up the roots which have been made higher up. Upon this I said—"What water do you use for the plants?" The reply was—"We use the water from the tank while we have any, but this now has been exhausted for a long time, and we use it from the pump in the house;" and this pump, which draw the water from an iron soil, had worked all the mischief, and the roots above the soil had also been scorched or sanked, in spite of the water used, and such may be the case with my friend and his *Oncidium splendidum*—his water may be too hard, and does not suit the plant. I know that this season has been an exceptionally hard one to preach about the use of rain-water: but a great store of it should be put by, and the pump-water should be reserved for damping down the floors and stages; but never let a drop of this be given to the plants, either from the watering-can or the syring, and by doing this there will be a greater quantity left to give the plants. Now this *Oncidium splendidum* I know is by many authors made but a variety of the beautiful and fragrant *O. trigynum*, which is the *Oncidium Barkeri* of others; but no two plants can be more unlike—in fact, they do not appear to have anything in common. In *O. trigynum* the huds are large and globose, bearing two or three leaves, which are some 9 inches long, membraneous and bright-green; the long spike bears some loose bunches, which are bright golden-yellow, beautifully fragrant, resembling *Violeta*. In *O. splendidum* the huds are small, bearing a single leaf, which is very stout and fleshy, keeled beneath, of a dull-green, which changes with age to a bronzy-brown. So far the plants are totally unlike; but I must admit the flowers are marked very much alike; but these are totally free from perfume. But if my readers will send me a few flowers from each kind through the coming winter I will endeavour to make a distinction between them.

MATT. BRAMBLE.

ODONTOGLOSSUM HARRYANUM.

I HAVE a letter from "An Eight-years' Subscriber" respecting this plant, and I may set his mind at rest about his having treated it quite correctly, although I do think it is rather too high a temperature to keep it in; but, at the same time, it requires, or does better in, a somewhat warmer atmosphere than many of the *Odontoglossums*. But about the flowers not opening and hiding their beauty, I thought I had drawn the attention of my readers to this great fault of *O. Harryanum*, and this blemish is the only drawback to this fine kind, and if my friend will simply put his thumb into the flower between the petals, simply spreading them out, this will give them a slight bend, and then they will remain as well expanded as any drawing in any book or other place, and, in fact, in all probability it was from a flower which had passed through the above process that the drawing in question was made, and I do not think it quite just to the gardener that a figure such as this should be given without some slight notice of the manner in which it has been obtained, because I do not think a single plant has yet flowered in the country which has given a well-expanded bloom. I have heard it suggested that this is a sign of its hybrid origin, and that it is a cross-bred plant. Now, I cannot see why this should be brought about by hybridisation, nor can I draw any inference as to the probable parents of this fine plant, for it certainly must be considered a very ornamental kind. If it just has the slight assistance given it, which I have previously noted, and this enables it to open, and to reveal its beauties, and many extraordinary varieties have from time to time appeared. The plant has not been known very long—in fact, a single decade has not yet passed since it first flowered in Messrs. Veitch's nursery, they having purchased it from Mr. Horsham, of Colchester, and from whom I learnt that many collectors had been quite close to the spot where it grows without ever finding it; so that I imagine its native haunts are very restricted, and from this plant having been so recently found there is reasonable hope yet of some more new and fine species.

Reichenbach said of this plant that "it is a fresh type, a grand and unexpected surprise," and to Mr. Sander we are again indebted for the species becoming popular. The spikes upon the old imported plants were between 2 feet and 3 feet in length, bearing many flowers, but as yet I never have seen anything approaching to this size under cultivation; indeed, there appears to be a lack of active resolution in the growth of this fine plant, which appears to have crept over most people, either in consequence of the plant being abundant and cheap, or because of the non-expanding of its blooms, as mentioned by the reader; but this may be overcome by simply proceeding in the manner above described, and the effect produced warrants the use of any method to successfully combat this one great failing in the plant.

MATT. BRAMBLE.

CHRYSANTHEMUMS.

SEASONABLE CULTURAL NOTES.

THE present is a busy time amongst the plants, no matter for what purpose they are cultivated. In spite of the extremely hot weather the plants generally are in a promising condition, the foliage is large, yet of that stout leathery appearance which betokens good blooms later on, if due attention is paid to the wants of the plants from this time until they are in bloom—"Teking" the huds and supplying the plants with stimulative food are the chief points at present, although many small sundry details press heavily upon the hands of those with many other duties to attend to in the garden. Bud-teking must be attended to promptly upon those plants grown to produce large exhibition blooms. If the shoots are allowed to grow several inches after the huds have formed in the point of each shoot they rob the bud of that support necessary to build up that amount of foundation to produce well-built, solid blooms—in fact, buds so treated do not swell at the early stage as they ought. A loss of force means less bulk in the blooms. Directly it can be seen that the bud is perfect in form, not having been damaged by insect pests in any way, the shoots clustering about it should be promptly removed, so as to concentrate the whole energy of the plant into this particular spot. The work of removing these succulent shoots is best carried out during the early part of the day, or evening, when the leaves are covered with dew; they are then less tough and easily snapped off if bent suddenly downwards with the forefinger of the right hand. A little practice will enable the cultivator to remove these shoots more expeditiously than by cutting them off with a knife. This is really the explanation of the term so liberally employed of bud "taking." Many amateurs do not understand its real meaning; they think it means taking the huds off. Much attention is necessary in removing all other surplus growths which spring from the joints below, consequent upon the natural channels of growth being diverted by the removal of the leading shoots. All shoots not required for the welfare of the plant should be promptly rubbed off, no matter from what part of the plant they come. If the stock of any particular variety is scarce, owing to its shyness in throwing up outtings freely from the base at the proper season, it is a good plan to insert some of these spare shoots, especially those coming from the soil, in sandy soil in a cold frame. From these small plants many outtings will be available next December. The minimum of trouble occasioned is time well spent. Feeding the plants should now occupy the attention of the cultivator. Do not adhere to one kind of food too long at a time. A change is most beneficial, and do not by any means give doses of any kind too strong; far better give it weak and often in preference to the reverse. During showery weather artificial manures, as Thomson's Vine manure, Clay's, or dissolved bones, are most valuable, a small quantity sprinkled on the surface of each plant once in ten days, allowing the rain to wash it in, is a valuable aid just at a time when the plants cannot be watered, owing to the continued showery weather. Root-water should be given at least once a week. This manure is a capital stimulant, improving the colour of the leaves, and with that increased quantity of the bloom must necessarily follow.

Where any plants exhibit a tendency to paleness of the foliage, as in the case of *Boele d'Or*, for instance, less water should be given these for a time until a change is apparent in the colour of the leaves. Too much water at the roots is more often the cause of paleness in the leaves. The roots are kept continuously in a moist state, which the constitution of particular varieties cannot withstand with impunity. E. M.

FRUIT.

APPLE "BRADDICK'S NONPAREIL."

REALLY good dessert Apples in season during the winter are none too plentiful, and it is equally certain there are a few varieties not so well known as their merits entitle them to be. Among those latter I would give Braddick's Nonpareil a prominent place, believing it to be one of the best dessert varieties that can be grown in a private garden. The fruit is medium-sized, flattish round in shape, skin pale yellow on the shaded side, and brownish-red where exposed, there being patches of russet about the eye and other exposed parts. The flesh is yellow, moderately firm, richly flavoured, and aromatic. It remains fit for table longer than most other Apples, as it can be had good from November till the end of April. The habit of growth is somewhat slender, the variety not being well adapted for growing in a pyramidal form, but succeeding well either as a half-standard or large bush—in either case on the Crab-stock—and it is also strongly recommended for growing on the broad-leaved Paradise-stock. I have a large freely-grown bush-tree on the Crab-stock, and it was part of a fruiting branch of this from which the photograph was taken and reproduced last season. For several seasons in succession good crops have been gathered, and the tree flowered more abundantly this year than ever previously, but, unfortunately, the buds had been badly injured by severe late frosts, the result being a complete failure. My soil is a strong loam, resting on a very retentive, clayey subsoil, and only Apples with a good constitution will long remain in a healthy, productive state unless lifted and replanted occasionally.

This has not been done in the case of Braddick's Nonpareil and several other trees owing to their great size, and because I consider tempering with them likely to do more harm than good. Allowing comparatively stunted old trees to form a limited number of fresh branches to replace the older ones will frequently put new life into them, and is the only reinvigorating measure that has been adopted in the case of the specimen of Braddick's Nonpareil. This variety would appear to be better appreciated in the south-western counties than in other parts of the country, and is to be seen at its best at the Exeter late autumn shows. W.

RASPBERRIES.

It is somewhat remarkable that such a humble fruit as the Raspberry should show such aversion to particular soils as to almost fail to grow, let alone produce fruit worthy of the name. As it happens, I have had to deal with Raspberries under diversified conditions, and the first difficulty I was called upon to solve was in a garden where almost every kind of hardy fruit could be grown to perfection, the Raspberry alone excepted. Considering what a useful fruit the Raspberry is, the want of a sufficient crop is likely to be felt in any garden where hardy fruits are grown. In many instances, however, without the disadvantages of an unfavourable soil the culture itself is often at fault. As a rule, the Rasp-

berry thrives best on open sunny loam well enriched from the surface with manure, or even what we may call alluvial deposits, such as secured from the receding of rivers, old sea beds, or such as reclaimed fen lands where well drained. They also thrive the most satisfactorily on those soils which are cool and moist, although it must not be surmised from this that stagnant moisture must be allowed, as I know of no other fruit which requires a freer drainage. In the garden that I had charge of, and where Raspberries had been hopelessly tried for upwards of twenty years, it was clearly seen that some

EXTRA SOIL PREPARATION was needed if they were to succeed. In this instance all the garden trimmings and refuse that I could get together were saved, the rougher being burned and the ash returned to the hulk. With this was incorporated some lime. The whole was laid up in a heap for twelve months and turned occasionally. This formed a capital rooting medium in which the roots rambled freely and threw up vigorous canes. Trenches 18 inches in width and the same in depth were taken out where each line of plants was to go, and into this the material was placed, the best of the surface-soil being placed upon the top. The canes having been planted and set down to within 6 inches of the ground just previous to growth commencing, fine and vigorous shoots were produced,

work, the earlier it is removed the better, so that direct light may be enabled to reach the younger and growing canes. The work must not be done roughly, as the lower leaves having perhaps partially been denuded of light they are easily broken, and as these are wanted to foster and feed up the buds for next year's fruiting, any rough usage will obviously be followed by weakened canes, or at any rate very little fruit will follow on these parts of the canes which have had the leaves thus early destroyed. H.

4372.—**Melons.**—There is no information given as to the treatment the Melon have received. We are not informed whether they are grown in frames or in a house trained to a trellis? They seldom go wrong when cultivated in a well ventilated house. Indeed, the most frequent cause of their damping off in frames is an overclose atmosphere and too much moisture. It is necessary to place each fruit on a tile or a piece of slate to keep it from the damp earth.—J. D. E.

—To be successful with Melons, several details of culture must be rigidly adhered to, or failure is sure to follow. First, the plants must not be crowded; space must be given for the leaves to develop to their fullest extent; one good shoot is better than half a dozen

weakly ones. Remove small useless shoots entirely, so that those remaining will have abundance of light and air. Secondly, when the female blossoms are expanded, they must be impregnated with the pollen from the male blossoms, which are easily distinguished by their being simply blossoms, whereas the female blossoms have a perfectly-formed fruit immediately behind the blossom. The middle of the day is the best time for fertilising the blossoms, so that the pollen is certain to be dry, otherwise the fertilisation will not be perfect. Thirdly, the plants must not suffer for want of moisture, either at the roots or overhead, or the fruit will fail to swell to even a fair size. Scarcity of moisture, both at the roots and about the foliage, is conducive to the presence of insect pests, such as red-spider and thrips. After the fruit is set and swelling freely, the foliage should be syringed twice daily; the roots kept moist; the character of the soil—heavy or light—will guide the cultivator as to how often the plants need watering. Persons who have had no experience do not know the result of carelessly wetting the stem of the plant. This cultural mistake causes the stem to cauter just below the surface, and eventually decays, thus spoiling the crop. The water ought not to be poured on the soil nearer than 2 inches of the stem. When the fruit is swelling freely, copious supplies of weak liquid manure will increase the size of the fruit considerably. I omitted to say that fertilisation will be accelerated if the soil is kept rather drier at the time when the plants are in flower, but not so much as to cause injury to the plants by the leaves flagging.—S. P.

4417.—**Caterpillars on bush fruits.**—The Gooseberry is frequently attacked with caterpillars, and when once they get upon the plants it is not easy to get rid of them except by hand-picking, which is a very slow, tedious process. The magpie-moth and the Gooseberry and Currant saw-fly both deposit their eggs on the bushes, and the larvæ feed upon the leaves. The last-named is the most troublesome. The eggs are laid in the spring to begin with, but successive broods are kept up until October. When the larvæ are full-grown they descend into the earth and form pupæ, from which flies emerge and stain the soil. The pupæ remain in the soil during winter, and they can be

OUR READERS' ILLUSTRATIONS: Fruiting-branch of Apple "Braddick's Nonpareil." Engraved for GARDENING ILLUSTRATED from a photograph sent by Mr. W. Cooper Junior, Marston, Frouce, Somersetshire.

which carried a fine crop of fruit the following season. In all cases where there is a difficulty in getting Raspberries to thrive I can commend the above as a means of getting out of the difficulty, although probably it must be taken into consideration that other prominent details will have to be attended to. Amongst these one of the most important is not to fork over the plantation at any time, as the Raspberry being a surface-rooter, the forking tends to disturb the rootlets. The soil being quickly exhausted by the numberless roots which prey upon it, nourishment must be provided by giving annual top-dressings of either manure or, what is better, the latter and garden refuse combined. This dressing also tends to keep the surface cool and moist, this being what the Raspberry delights in during the summer months. Given generous treatment then, the Raspberry will well repay the cultivator for the trouble bestowed upon it. It must not be surmised that the soil or surface culture is all that is needed, for although the Raspberry is naturally a shade-loving subject, yet where the canes are allowed to grow into a crowded mass for the want of timely thinning, the heads fail to plump up on account of loss of light. The first stage of thinning consists in cutting off with a hoe during the early months of summer all rambling suckers growing away from the stools; and again at this season of the year going over the plantation and cutting out all old fruiting wood, as this having done its

destroyed by clearing the soil from under the bushes to a depth of 3 inches or 4 inches. It must be placed in the bottom of a trench, and fresh soil from the trenches put in its place. Fresh tan from the tan-yards placed under the bushes and dug in is a good remedy.—J. D. E.

— When the leaves fall, take off 3 inches or 4 inches of the top soil under the bushes, give a dressing of lime and manure, and take fresh soil from some other part of the garden, where no bushes are planted, and fill beneath the bushes. Bury the soil taken away in a trench 2 feet deep, so that the insects, when they move in the spring, cannot work their way out.—E. H.

— Any time during the month of February the bushes should be entirely coated over with a mixture of lime, soot, and clay made into the consistency of paint. If this mixture is put on alone the frost will most likely take it off, but if a handful of any kind of kitchen fat is added to every half gallon of the mixture, the whole made warm and applied with an ordinary sash tool as used by painters, there is little fear of its washing off then. This may seem a slow process, but it is a certain cure not only for caterpillars, but it prevents the birds picking out the buds, which is in itself a source of great annoyance in many gardens. Should there be a few caterpillars put in an appearance in the spring when the fruit commences to swell, a handful of hellebore powder, sprinkled on that part of the tree during the evening, will settle all it comes in contact with. Great care, however, should be exercised in the use of this chemical, as it is of a highly poisonous nature. The proper plan is to thoroughly wash the bushes the next morning with clean water, applying it with some force through the garden engine or a syringe, cleansing the trees both from powder and caterpillars at the same time.—S. P.

434.—Strawberry border.—An I write these lines I am preparing a Strawberry border by trenching up a piece of ground from which a crop of Pasa has been gathered. The subsoil is not very good, and I only work the ground to a depth of about a foot. Some good manure is placed at the bottom of the trench, and a little more is worked in with the soil nearer the surface. If the young runners are layered in flower-pots and are planted out early in August, they will carry a full crop of fruit the following season. The sooner they can be planted out the better, as the larger plants produce the greatest weight of fruit, and the quality is also better. All runners must be removed from the young plants as soon as they are formed.—J. D. E.

436.—Grapes splitting.—Great Colmar Grapes have not so much tendency to split as some others have. As the Vine is grown in a pot, the cultivator has complete control over the roots, and ought to be able to prevent any variety of Grapes from splitting. It is caused by the roots taking up too much moisture—that is, if the berries are in perfect condition. The cure for it would be to withhold water as soon as the berries show signs of the skin cracking. Rust or mildew on the skin will also cause the berries to burst, as the skin on the diseased part will not swell at the same rate as the healthy part.—J. D. E.

440.—Melone splitting.—The most frequent cause of Melone splitting is a damp, confined atmosphere. When an indication of splitting shows itself the structure in which the plants are growing should be ventilated at night, and less water given to the roots and foliage. This treatment will invariably prevent any more fruit cracking. It is the sudden admission of air after the frame or house has been closed for several hours that causes a contraction of the skin, and the more rapid the change in the internal atmosphere the more the fruit cracks.—J. C. C.

— Some varieties of Melons are more liable to be injured by the fruit splitting than others. The small scarlet-fleshed variety Scarlet Gem used to be a bad one, and seedlings from it have this fault, which is a serious one. Careful cultivation may do much to counteract the evil. It is caused by watering too much when the fruit begins to ripen, especially if the plants have had a check by being kept rather dry. This has the effect of hardening or contracting the skin, and the fruit cracks more readily when water is applied (freely) to keep the plants

growing steadily from the first, well irrigated, and freely watered. As the fruit approaches the ripening stage do not give so much water, and if the plants are carrying a good crop of fruit it seldom cracks. Should there be any signs of it cracking, the last resource is to sever the stem on which the fruits are half through. This prevents the overflow of sap, and will prevent the fruit from cracking in most instances.—J. D. E.

— This generally occurs just at the time when the fruit is changing colour, and is owing to two reasons. First, the plants are allowed to get dry at the roots, and then the soil drenched all of a sudden, which causes a too free a rush of sap to the fruit. Secondly—and the more likely reason—the atmosphere is kept too moist and warm when the fruit is at the changing period. Melons need a warm, buoyant atmosphere, not only to ripen the fruit, but to give it flavour and prevent splitting.—S. P.

— A slight check from drought, and then heavy watering, will cause Melons to split. Deficient ventilation, especially keeping the house or frame closed late in the morning, will do it. The remedy is to alter the conditions under which they are grown.—E. H.

442.—Hedge of Gooseberries.—It is not likely that you will be able to get bushes of a bearing size trained in the way you propose. There is, however, no difficulty in starting with young trees to bring them into the form you want, as any nurseryman would make a suitable selection for you. Early Sulphur will probably make the best sordid form, as the growth is stiff; but others will not be difficult if you commence training the branches while they are young.—J. C. C.

— Gooseberry-bushes with a strong base may be bought in any nursery, and this is all that is required to begin with. If strong bushes are planted in good soil they will soon form three-branched cordons. If all the shoots except the leaders are cut out and the others permitted to grow as they please, care being taken that the branches are properly trained in as they grow.—E. H.

443.—Apple Lord Suffield in flower.—It is very unusual for an Apple-tree not to flower in the spring and to produce a full crop of blossoms in autumn. It is not at all unusual for Apple and other trees to produce blossoms in the autumn as well as in the spring. There may be something uncommon in the position of the tree in question; but its blossoming may be caused by the tree making a second growth after the excessive drought of April, May, and June. Lord Suffield Apple does not succeed in all kinds of soil and some of the best growers for market are planting Lord Grosvenor instead as an early Apple.—J. D. E.

— Although it is unusual for Apple-trees to develop their blossoms during the present month, it is by no means extremely rare, and certainly not the advantage of the tree that the blossoms are expanded. The effect such immature blossoming will have upon the tree is that the next year's fruit crop will be most likely lessened, if it bears any fruit at all. The buds cannot plump up and ripen sufficiently in such a short space of time. It would have been a wise plan to have picked off the buds directly they were visible, instead of allowing them to expand.—S. P.

— It is not uncommon for this and other kinds of Apples to flower at unreasonable times. I have often met with similar cases—know of several near where I am writing. The season has been out of joint.—E. H.

449.—Apple Cox's Orange Pippin.—It depends very much upon the season as to the time for gathering this fruit. Mine is now ready, but at other times it will hang until the end of September. If this or any other Apple is gathered before being ripe the fruit shrivels. A good test of ripeness is to pick a fruit from the most shaded part of the tree, cut it open, and if the pips are brown all the crop may be safely gathered.—J. D. E.

— Seasons vary very much, as the present one has proved, in the matter of ripening Apples. Many sorts are thrown out of their usual season fully a month by the extreme heat and drought. As a rule, this Apple is not ready to gather until the end of September in the south. However, the best guide is to examine the fruit occasionally, cutting one in two that apparently is healthy; if the pips are brown in colour, and the Apples part easily from the stem, the crop may be gathered and stored carefully. If the fruit is picked before it has really matured, the

Apples not only fail to keep properly by shrivelling, but that rich orange flavour which characterises this variety is absent.—S. P.

— This variety usually ripens some time in October, throughout the southern counties, earlier or later, according to the season.—B. C. R.

4365.—Vines in pots.—Seven-inch pots are not large enough for Vines to fruit in. If they are strong the pots should not be less than 11 inches across the top; the weaker canes would do in pots six inch less. If the plants are in free growth at the present time they ought to be potted at once, but if the canes show signs of ripening at the base they ought not to be potted until next February. When the canes are well ripened, say, towards the beginning of September, they should be stood out-of-doors at the foot of a south wall and freely supplied with water during hot and dry weather. The pots ought to be protected from frost during the winter with leaves or partly-decayed manure.—S. P.

4834.—Early Strawberries.—If strong plants are turned out of pots any time before Christmas a good crop of fruit may be gathered by the next May. Noble is a good kind for the work; the fruits are large. Sir J. Paxton also is a good sort. It is no use to depend upon weakly plants. They will do better planted in the border. The lights need not go on till February or March.—E. H.

— Noble is the most productive and most handsome of the early kinds; but if you want the fruit for your own use I should advise you to grow Black Prince or Gibraltar and Keen's Seedling instead, as these are far before the other in points of quality and flavour. To obtain a full crop, runners should have been planted in June or July at the latest; but it is not too late yet, and if you can get good strong runners with some earth on the roots, or established in small pots, they will yet produce a moderate crop next summer. The frames can be placed over the plants about the middle of March, or as soon as they begin to move. If a succession of fruit is wanted, cover a few at intervals until the middle or end of April. Nothing would be gained by employing pots, on the contrary, those in the ground will produce double the weight of fruit with a quarter of the labour and care in watering, &c. Careful ventilation is the chief point.—B. C. R.

4420.—Pears.—It does not answer to pick Pears unripe, for they shrivel and are not worth much. On the other hand, it is not well to allow the late Pears to hang too long. Pitmaston Duchess is not a late Pear, and should be gathered as soon as the pips begin to get brown. Maréchal de la Cour is also an October Pear. Late varieties, such as Josephine de Malines and Knight's Monarch, should be gathered about the end of September; there is nothing gained by letting them hang later.—J. D. E.

— The Pears named in the list given will not ripen on the tree, so as to be in a condition for use. They would fall off, of course, but would not get soft or mellow till they had been laid up somewhere. If a Pear is ripe enough to gather from the tree, in the case of late kinds several months before their season for use comes round, and such Pears must, of course, be laid up somewhere, and the best way of keeping choice late Pears is to wrap each fruit carefully in paper, and pack in boxes or barrels and store in a dry cellar, where there is not much fluctuation of the temperature. When the season for their use arrives take them out of the barrel or box and move to a temperature of 60 degs. to 65 degs. for a few days, and the flavour will come splendidly. To tell when a Pear is ripe lift it up in the hand and bring just a little pressure to bear upon the stalk. If the Pears are fit to gather the least pressure brought to bear upon the junction of the stalk with the tree will cause a separation. If it does not do so the Pear is not fit to gather. The Pears from any grown tree may be made to last in season much longer if the season of gathering is spread over several weeks, instead of being, as they usually are, all gathered at one time. This is so self-evident that words need not be wasted about it.—E. H.

4410.—Siberian Crab preserve.—Take 9 lb. of sugar and put it in a preserving pan with a pint of water. Boil to a thick syrup, stirring constantly to prevent burning. Now add a dozen pounds of the fruit, and stew until the liquid is done in this way they are most delicious. —B. C. R.

THE KITCHEN GARDEN.

WHITE AND BROWN SPANISH ONIONS.

UNDER this heading may safely be included a large number of forms, differing very slightly, if at all, from each other, but all of good shape and serviceable. When first sent out, the so-called novelties do surpass the older forms, but in the course of a few years the stock appears to deteriorate, this confirming me in the theory that the superiority rests more with the better grown seed and the extra attention to cultural details than from any inherent and fixed qualities they possess. In the case of seed-saving from novelties, the bulbs are all well selected and

Onion "Blood Red" or "Flat Italian."

carefully ripened, while the greatest care is bestowed upon them when producing seed, the consequence being that an extra good stock is available for distribution. The commoner forms receive very different treatment, the principal aim being to save as much seed as possible, the lowness of prices forbidding any extra pains being bestowed upon them. Personally, I always prefer to pay a fairly good price for the best seed, being well assured this will germinate more surely and strongly, and the subsequent progress of the plants be far more satisfactory than in the case with inferior seeds and what results from it. I may be wrong in my deductions, but I have not met with anything to surpass the stock of true White Spanish as sown and grown for many years past by a friend in Dorsetshire. Had he so chosen, he might have exhibited it repeatedly, and then have sold it as a distinct and new form, but it would have been a good stock of the true White Spanish Onion (see cut) all the same. A good bod of Onions is always an object of pride with most gardeners. Exhibitors generally have adopted the plan of raising a considerable number of plants in boxes, the seed being sown early in February, transplanting to the open taking place towards the end of April. Although quite small when thus put out, they are yet considerably ahead of any obtained by sowing seed in the open ground, and this gain is subsequently more than maintained. The plan of sowing seed in the autumn with the Tripolis, subsequent treatment also being identical, also results in the formation of extra large and early bulbs, but these usually become much too coarse and ugly; whereas those raised in the spring mature nearly as early and are far more taking in appearance. A rich yet solid root-run is necessary for the production of firm, short-necked, long-keeping Onions—this, whether the seed is sown where the plants are to grow or transplanting is resorted to. Wall-grown, early-matured bulbs of the White or Brown Spanish types present a very clean appearance, the necks being small, but, as a rule, they are somewhat flat and often rather hollow underneath; consequently they do not weigh particularly well, and lose ground in competition with the newer forms of a different type with well-rounded bases. Nor do they keep over well. Properly harvested, bunched, or roped up, and kept cool and dry, the season may last to March, but rarely extends far beyond that month. As regards table quality, little or no fault can be found with them. Two other good Onions are the Flat Italian (see above) and Paris Silver (see page 374). The latter is excellent for pickling. G.

TOMATOES FOR WINTER.

WHERE Tomatoes are looked for during the winter months, it will depend entirely upon how the plants are treated during the next month or two whether they will turn out satisfactorily or not. Beside healthy plants, a light and well-heatad structure is needed, this being one, if not the principal, point to ensure success. It is rarely that Tomatoes succeed well when grown in stoves or pits with other things, as the conditions suitable for the one are not adapted for the other; consequently they fail. Narrow Cucumber and Melon-houses are very suitable, as these invariably are well heatad, also light, and with provision for affording a circulation of air. Indeed, as the plants of these latter are cleared out the Tomatoes will take their place, not, however, by planting them out, but by standing the pots on the hilloeka after being levelled down. The roots would ramble out into the beds, and the warm root-run would greatly benefit the plants. The latter should now be established within the next week or ten days in their fruiting-pots, and if the structure is not ready to receive them, take care that they are not neglected by being crowded up with other subjects. The best position in the meantime is in a light and airy greenhouse, where the atmosphere is warm and buoyant. Nor must the growth be crowded up by being allowed to ramble anyhow. The main leaders, and it matters little whether they are single or tripla cordons, must be kept thiuily disposed, and all side laterals be kept closely pinched out. As the trusses of flowers form, attend to the setting if there should be the least sign of their falling. The earliest trusses must be scoured and those that follow throughout the next month, as after this they rarely set satisfactorily until the turn of the year again. When the summer fruiters are healthy, and they are growing in light and well-heatad structures, these often turn out very satisfactory for winter work. The older growths should be cut out and younger laterals encouraged. By attending to thinning, stepping, and setting of fruit, a good supply would most likely be obtained throughout the winter. To give the plants a fresh start, the old surface soil could be removed, replacing with a top-dressing of loam, pulverised horse-droppings, and a little charcoal. If pressed firmly, surface roots will form freely, and assist in giving the Tomatoes a fresh lease of life. Care must be taken that artificial heat is kept up, as at this season when the nights are cold disease may possibly attack them. Y.

4412.—**Woodlice v. Mushrooms.**—This is a very troublesome pest in the Mushroom-house, and cannot be easily got rid of. The best plan is cleanliness. In the summer-time, when the house is not in use for the Mushrooms, have it well cleaned it out; remove every scrap of rubbish that might give them shelter. My house is entirely fitted up with slate slabs on iron supports for the Mushroom-beds. If this troublesome pest appears in the winter it must be trapped by putting a bait of boiled Potato in a flower-pot laid on its side. A little dry hay in the pot will attract the woodlice. They go in to feed at night, and, feeling comfortable in the dry hay, they remain, and may be shaken out and destroyed next day.—J. D. E.

— Keep a few loads in the house, and at this season, before the autumn beds are made up, clear every bit of loose matter out of the house, whitewash the walls, and pour boiling water in every corner and crevice. If this were well done once a year, woodlice would not give much trouble.—E. H.

4414.—**Onion fly.**—Prevention is much better than cure when we come to deal with this troublesome pest to the cultivator of Onions, for when the maggot has once got into the Onion there is no way to destroy it—in fact, it will destroy the Onion. Therefore, the first step towards prevention is to get out all Onions as soon as it is seen they are attacked, and destroy them with the maggots to prevent their getting out, and turning into pupae in the soil. The flies are produced from the pupae in early summer, and lay their eggs on the plant near the soil; the larvae soon emerges from the eggs, and bore into the ground close to the Onion until they reach its base, when the work of destruction begins. Soot applied to the ground is a good thing; this and gas-lime may be dug into the ground in autumn, and the soot may be applied in the spring when the plants appear

above ground. Water the plants with a solution of paraffin at the rate of 2 oz. to a gallon of water. Trenching the ground deeply in winter buries the pupae out of reach, and they die when deeply buried.—J. D. E.

— The best remedy I have ever used has been soot, to be dusted over the young plants end of April till end of May. Virtually there is no remedy after the flies have laid their eggs on the plants; the soot makes the Onions distasteful, and so the fly avoids them. Possibly paraffin and water or some strong insecticide used whilst the eggs were accessible might destroy some of them, but the application must be well-timed. After the eggs are hatched and the maggots are working down to the roots nothing can save them. A good deal of help may be given by using stimulants, such as nitrate of soda, to rush the plants past the time during which the attack lasts.—E. H.

4415.—**Parsley.**—No doubt this is due to the intense heat and drought. The only way to prevent the same thing occurring under similar circumstances would be to shade the plants in some way—a little straw or Fern thrown over the bed would doubtless have saved it. Water the plants well with water, in which a little nitrate of soda has been dissolved, and afterwards with pure water. This will probably start them into growth again.—B. C. R.

— Parsley suffers from drought in poor soil, and a check sometimes leads to canker or insect attacks. Wood-ashes has good effect on keeping Parsley free from canker at the collar, and watering with soap-suds tends to prevent attack from insects. It is too late to sow again now, but it is possible if some of the roots were taken up, dipped in strong liquid-manure, and planted on a south border, they would start away in the fresh soil and make a lot of useful growth before winter. If the plants are cleared where they stand of all discoloured leaves, and well soaked with soot-water, a beneficial change will be effected.—E. H.

— It may be caused by the extreme drought experienced of late if the roots are growing in shallow or otherwise badly-cultivated soil, or the cause may be due to grubs at the roots. This is a very common cause of Parsley dying off at this season of the year. If the latter is the true cause water the roots thoroughly with water, to which is added petroleum at the rate of one wineglassful to three gallons of water. In some localities the young roots of Parsley are so affected by grubs as to necessitate a constant use of this insecticide in the autumn.—S. P.

— Doubtless this has turned brown owing to the dry weather. Many good gardeners complain that Parsley has done badly this year. It likes good soil and sufficient water at the roots. In ordinary seasons it is easily grown.—J. D. E.

4420.—**Gas-lime and wire-worms.**—I am not sure that gas-lime is the best material to destroy wire-worms, but farmers have great

Onion "White Spanish" or "Reading."

faith in it and use it extensively. They put on about 15 owt. to the acre. A good coating of soot applied so that the rain may wash it in at once is excellent. The ground should also be frequently harrowed and rolled, which exposes the wire-worms to birds, and the rolling may kill some of them. They do not like gumo, and this, if washed in by rains, is a good remedy. I advise stirring up the ground frequently during winter, and a great many of the worms would be removed with the Potatoes.—J. D. E.

4379.—**Tomatoes curling up.**—Tomatoes are attacked with mildew, caused by deficient ventilation, and hastened by damp conditions of the weather since the drought broke up. Cut most of the leaves close to the pair of leaflets. The fruit will ripen.—E. H.

TREES & SHRUBS.

NOTES ON FLOWERING SHRUBS.—II.

FLOWERING in mid-winter, when everything is bare around, save for the little winter Aconite, the Japanese Wych Hazel, as *Hamamelis japonica* is familiarly called, deserves a good note, although not a well known shrub. But it is the things that everyone does not grow that I wish to bring before the notice of my readers. The Japanese Wych Hazel is a dwarf tree, perfectly hardy, deciduous, and loving the sun. It gets its name from the likeness of its leaves to those of the Hazel, but it is when these have not yet appeared that the golden flowers reveal their beauty, studding the naked shoots, the petals twisted, and the calyx, although small, is in evidence from its crimson colouring. One tree in the garden is perhaps sufficient, but the *Hamamelis* is worth recognition. A glorious garden shrub, with a terrible name, is *Hydrangea paniculate grandiflora*, and it succeeds in ordinary gardens. One bush of it on the turf makes a beautiful effect in autumn, the heavy clusters of white flowers being much larger than those of the common *Hydrangea*, and the growth will be of great vigour if the soil is made rich. When the shrub is in perfect health it will grow about 4 feet in height, and is borne down in summer with its burden of flowers. The great point is to keep the old shoots out away so as to throw vigour into the new growth. A wealth of beauty is contained in the *Magnolias*. The glorious *M. grandiflora* that one usually sees against houses is not the only species that deserves a place. I know from experience that even in suburban gardens the early-blooming *M. conspicua* will give a good account of itself. This flowers quite early in the year, before even the leaves have appeared, and the blossoms are like white cups, thickly covering the leafless branches. A specimen of it in front of an evergreen shrub is very charming, and the bloom is in a measure protected from unpleasant weather trials. An interesting variety, a little later in blooming, is *M. conspicua Soulangiana*, the flowers touched with rose-purple and of similar expression. *M. glauca* is a handsome tree, the bold foliage retained throughout the year, white, fragrant flowers that appear in midsummer being its chief characteristics. A healthy specimen of it on the lawn is a distinct gain to the garden. This small selection of *Magnolias* will be ample for all ordinary gardens, but the list can be easily extended by adding such fine things as the *Cucumber-tree*, *M. acuminata*, and *M. umbellata* or *M. triptera*. Very distinct from the *Magnolias* are the *Mock Oranges* or *Philadelphuses*, commonly called *Syringes*, but why is not exactly evident, as the *Lilac* is the *Syringa* proper. Still that is a matter of small moment. It does not detract from the beauty of the *Mock Oranges*, each flower like a magnificent *Orange-blossom*, just as sweet, making the garden a fragrant spot. One often wanders into an old-fashioned garden in the summer and smells the *Philadelphuses* many yards off—a rich, agreeable perfume, too heavy almost when the shoots are out for the house. These shrubs are normally crowded up into shrubberies, but thus barbarously treated they are deprived of their true elegance and beauty. Beside varieties of the common *P. coronarius*, the species most frequently planted, there is another flower which is adapted peculiarly for small gardens, as it does not occupy much space. This is the small-leaved *Mock Orange* (*P. microphyllus*), the smallest of the genus, the leaves no larger than those of the *Myrtle*. A specimen of it on the lawn is full of beauty, the branches toning the Grass, and wreathed with white flowers, delicately scented and full of grace. It is quite hardy except in the coldest localities, and is one of the most precious shrubs that we have had from New Mexico. The *Philadelphuses* succeed best in fairly light soils and sunny positions. Another very charming class is that formed by the *Viburnums*, or *Guelder Roses*. The common *Guelder Rose* is one of the most graceful of dwarf-flowering trees, and its aspect when in bloom is too familiar to need description, but we have also the Chinese *Guelder Rose* (*V. plicatum*), a beautiful garden shrub, stiffer in growth than the commoner type, and more spreading. The creamy-white bunches of flowers are used thickly on the branches, and a distinct contrast

to the deep-green wrinkled leafage. A light soil and moderate shelter are the chief requirements, and under these conditions a wealth of bloom may be expected each summer. Its freedom in blooming is most marked. I have seen a shrub so thickly covered with flowers as to prevent the leafage, except here and there, being seen. It is the fashion, unfortunately, to cling to one kind of thing too much in gardens, but I am afraid the truth is that the gold-mine of beautiful flowering shrubs and trees has not been worked. Take the *Robinias*, or *False Acacias*, for example. The common *Acacia*, sometimes called the *Locust-tree* (*R. pseudo-acacia*), and it will be found in the majority of gardens. It deserves popularity, being beautiful in leaf and flower, hardy, and of quick growth, but a word may also be said for such a priceless treasure in the way of flowering trees as the *Rose Acacia*, *R. hispida*, a glorious species from North America, that should be planted in even quite small gardens, whether in the vicinity of large towns or in the pure air of the country. I enjoy the picture of a good specimen in full bloom, when its rich rosy-coloured flowers are in perfection in the leafy month of June, and it will grow in ordinary soil and situation. The great thing is not to plant too near high roads, as passers-by are apt to take of its flowery treasures, so profusely borne. One may also choose some of its varieties, but the type is sufficiently beautiful, and the possessor of the small garden may be content with it. The

Spiræas are a valuable family, and there are many of them all more or less beautiful. The trouble is, in fact, to know what to select and what to avoid. A species of much interest and beauty is *S. arifolia*, a North American shrub,

Onion "Paris Silver-skinned." (See page 373.)

usually rising about 6 feet in height; but it will grow most when in a thoroughly good soil and position. It is slender in growth, and is one of those things completely spoilt by being crowded up in an ordinary shrubbery, as one then loses entirely its characteristic elegance. A specimen on the lawn is unfettered by stronger growing neighbours, and a profusion of the fine plummy clusters is produced in the height of summer. If only one *Spiræa* can be grown, my choice would be *S. arifolia*, but the genus is so rich in beautiful things that one likes to have *S. Bumalda*, which is quite dwarf, not more than 2 feet in height, the flattened clusters of flowers being of a rosy colour, whilst also useful are *S. Douglasi*, *S. calcifolia*, or the Willow-leaved *Spiræa*, the dwarf *S. callosa* (deep-pink flowers), *S. Reevesiana*, *S. Lindleyana*, and *S. Thunbergi*. A golden rule in growing *Spiræas* is to have the soil moderately light, and the position sheltered. The fault of small as of large gardens is their monotonous aspect and absence of variety in the things planted. Common subjects are repeated until the eye rests with relief upon any subject out of the normal routine, therefore there is justification for enumerating many trees and plants not always seen, and not always grown well. Even now there is room for the Syrian *Ihiscus* (*H. syriacus*), in one or more of its many beautiful varieties, the double *Yellow Jew's Mallow* (*Kerria japonica*), very pleasing against a wall, *Olestra Haasti*, the *Rhus* continuo, or *Sinbad*, the *Snowdrop-tree* (*Halesia tetraptera*), so called from its *Snowdrop*-like flowers, *Laburnums*, *Weigelas*, the Japanese *Quince* (*Cydonia japonica*), and the exquisite *Amelanchier*, or *June Berry*. All are worth planting, and any one of them may be selected with the full knowledge that it will give pleasure.

4359.—*Choiysa ternata*.—This *Choiysa* is commonly called the Mexican *Orange-tree*; the blossoms are very like those of the *Orange-tree*. Where it succeeds in the open it is a capital subject to plant at the foot of a low wall or fence, or even growing as a bush in a sunny spot in the mixed shrubbery it is ornamental. In all the southern counties it is quite hardy, when receiving the protection of a south wall, at any rate. With me it generally flowers twice yearly; the fullest crop is, however, borne in April or May, when the plants are one sheet of pure white blossoms, which is much enhanced by the deep green of its foliage. Propagation is easily effected by means of the short, half-ripened shoots in the spring, taken off with a heel, if possible, inserted round the edge of a 3-inch pot, using sandy soil and plunging the pot in a gentle bottom-heat; afterwards gradually harden off until they will stand out-of-doors entirely. Any ordinary garden soil will grow this plant, providing it is broken up deeply, allowing the surplus water to pass quickly off from heavy rains during the winter. Abundance of water given to the roots during hot and dry weather will facilitate the growth very considerably remembering that if the growth is free in a like manner will the flowers be produced. But little pruning is necessary; rather tie the shoots in to the wall closely; more flowers will then be had. As a pot-plant for the greenhouse this *Choiysa* is valuable. By planting in too rich soil the growth will be short-jointed and firm. Stand the plant out-of-doors during the summer to ripen the wood thoroughly, and thus procure a full crop of blossoms.—S. P.

4376.—*Cutting back Hollies*.—The month of February is a good time to prune *Hollies* of any kind. There is but one reason why they may not be done at Christmas, or even earlier, and it is this, that the plants will look bare and unsightly during the period when evergreen shrubs are the most valuable—viz., during the winter. *Hollies* of any size are quite amenable to being closely pruned, and are very often more vigorous in growth afterwards, especially if the soil about the surface roots can be replaced with some fresh material, adding manure to it liberally. Liquid-manure given to the roots during the month of March is a capital stimulant to *Hollies* of any kind.—S. P.

4119.—*Mountain Ash berries*.—Dip them in ordinary varnish, and hang up till dry. Wax would answer the same purpose, or anything just to exclude the air.—B. C. R.

ROSES,

4135.—*Culture of Roses for exhibition*.—According to your statement you have already 250 plants of nearly as many varieties, none of which appears to give you such large flowers as you desire. It can hardly be that amongst so great a variety that you have not got a good number of sorts suitable for exhibition. That being so, does it not occur to you that the want of size in the flowers is through some fault in the management? Either your ground is not strong enough or some of the details are not understood. Where the fault is it is impossible for a stranger to say, but that it is in the direction indicated is pretty clear. It is important for you to bear in mind that is looking for size in individual varieties you are in danger of introducing a degree of coarseness in the flowers that is undesirable. Such naturally big roses as *Her Majesty*, *Earl of Dufferin*, *Paul Neyron*, and *Captain Christy* are not improved for exhibition purposes by any special treatment. Presuming always that the plants are judiciously treated, amongst the H.P.'s you will get size and quality associated with good form in such sorts as *Alfred K. Williams*, *Ulrich Brunner*, *Mrs. J. Laing*, *Marie Beaumant*, *Victor Hugo*, and *Marguerite de St. Amand*. Your selection of Teas do not please me greatly for open-air culture. I should discard *Niphetos*, *Madame Charles*, and *Catherine Mermet*, and substitute *Countess of Folkestone*, *Princess of Wales*, and *Perle de Lyon*. I should prefer *Luciole* or *Anna Olivier* to *Jeanne Ducher*, which is very good under glass. In the half-open bud state *Madame Charles* is very beautiful, but in a warm room or tent quickly expands and shows a prominent eye. Seeing how moderate your ambition is when you say you will be content with a stand of twelve blooms, you make it very clear that you are growing too many

varieties, you would do better with a less number. You want six plants of most of the sorts you grow, and to get a stand of twelve thirty varieties would not be too many to select from on a given date. However, if you add twelve to your present stock, with six plants of each, you ought to take a winning place if other things are equal. With regard to pruning, you must cut the Teas back nearly as hard as you do the H.P.'s, leaving five buds on the former where you leave three on the latter.—J. C. C.

4433.—**Manure for Roses**.—Looking at the liberal way in which you treat your Roses, I think you will act wisely if you discontinue the use of pig-eye manure, as it is of such a strong odorant that it is likely to promote undue luxuriance, and then severe frost might injure the plant. With regard to budding, I think it is an advantage if you remove the surplus buds as soon as they are formed. So many people allow the buds to get quite large before they remove them, that they cannot judge correctly whether it is a good plan or not. The following twenty-four varieties of H.P.'s I selected last year from a first prize collection of seventy-two as the cream of the lot: Alfred K. Williams, Ulrich Brunner, Alfred Colomb, Henri Schnitzius, Earl Dufferin, May Quennell, La France, Marie Beaumann, Marie Finger, Mrs. J. Laing, Her Majesty, Duchesse de Bedford, Emilie Hausburg, Comtesse de Serenyi, Mrs. Jowitt, Charles Lamb, Merveille de Lyon, Françoise Nobelen, Mme. Gabrielle Luizat, Marguerite de St. Amand, Duo de Rohan, Duke of Edinburgh, and Fisher Holmes.—J. C. C.

4416.—**Tea Roses**.—There are many Tea Roses as large as those you mention; but it is as well that you should know that many of the largest have a somewhat pendent habit—that is, the flowers droop when fully expanded, and what is wanted is that they should stand erect, as in the case of such varieties as Perle de Lyon, President, and Mrs. James Wilson. You will find the following good large flowers, and in most cases freely produced: Comtesse de Naidillan, Jules Finger, Inciole, Mme. de Wattoville, Mme. Jules Margottin, Sombrenil, The Bride, and three first mentioned.—J. C. C.

4423.—**Roses against a wall**.—Your wall is not high enough for such a strong growing Rose as Gloire de Dijon. A height of 20 feet suits it better. Instead of cutting back the strong shoots now, cannot you bring them down in a more horizontal direction? They will then flower next year at nearly every eye along the branch. If you cannot do this you must cut off the tops down to the height of the wall. At the same time, put in a plant of Marie Van Houtto by the side of the other, and in a year or two remove the one you now have. If yours is a good soil you will always have the same trouble that you complain of now, and Marie Van Houtto is nearly as free to bloom as our old friend the Gloire.—J. C. C.

4375.—**Border of Rose**.—Pray do not attempt to bud upon Manetti-stocks in the state you describe yours to be. If you do there will be a constant nuisance with suckers, which are certain to push up from the old stools and destroy all prospects of satisfactory results. Grubbing them out, renovating the border and planting afresh is the only chance of future success under such circumstances.—P. U.

4358.—**Roses in small pots**.—I like to see Roses grown and flowered in small pots. I have had nice plants of Tea Roses flowered in 5-inch pots. The plants were struck from cuttings, and they grew very vigorously and flowered splendidly. I repotted some of them into 7-inch and 8-inch pots, and they were most satisfactory. Others were planted out, and most of them grew with great vigor. Large, handsome specimens can be grown and flowered in 8-inch pots, and they will do very well indeed in 6-inch for one season, and should be repotted afterwards. They should have good potting-soil—good yellow loam, four parts, one part leaf-mould, one part decayed manure, with some coarse sand, and a 7-inch pot full of powdered bones to each barrow-load of the compost.—J. D. E.

HOUSE & WINDOW GARDENING.

MYRTLES FOR A WINDOW.

To show off brilliant-flowering plants in a window a background of green is often needed, and there are few better plants for this purpose than Myrtles, which always look handsome, while they should become highly decorative themselves during their blooming season. They accommodate themselves well to the conditions of life in a window if given plenty of air, and their foliage is kept thoroughly clean. In the larger-leaved varieties this is not difficult, as a soft hit of sponge can be employed to wash the leaves with pure warm water, if there be no blight on the plant, and a little soft-soap and Quassia, if necessary; but when the smaller-leaved kinds of Myrtles are grown this process of sponging becomes tiresome, and syringing must then be resorted to, or the plant can be placed out in heavy rain when it needs cleansing. To induce a Myrtle to flower freely the wood must be thoroughly ripened in July and August, when the plant should stand out-of-doors in a position where it obtains plenty of sunshine and watered regularly, for any failure in this may make it drop its leaves. The pot should be plunged to the rim in a bed (or box) of fine cool-shales, for the action of the sun on the roots which cling to the pot would be disastrous, although the plant itself must be well exposed to it. Kept rather dry and cool through the winter, in any place from which frost is excluded, and repotted in March, the Myrtle should be covered with bloom during the summer, its beauty and fragrance being remarkable.

CUTTINGS are easily grown in summer, either in moist sandy soil in pots covered with a bell-glass (or a tumbler in the case of a single slip), or in a bottle of water, where the roots will strike freely, and the plant can then be transferred with care to a small pot. Any ordinary potting compost of loam, leaf-mould, and sand, with a dash of soot (not exceeding a twentieth part of the whole), will grow them well, and liquid-manure in the shape of soot-water will help them much during the summer months, when in rapid growth, if given not more than twice a week in a thin, clear state. L. R.

The Nemesea.—From what I have seen of this new annual it is a very charming kind. I know the readers of GARDENING are interested in the new plants, flowers, or fruits that are introduced, and therefore a note on the comparatively new Nemesea strumosa Sutton will be welcome. It was introduced by Messrs. Sutton and Sons, of Reading, from South Africa about four years ago. I saw the first plants in flower and felt convinced that the Nemesea would get very popular. It is unlike the ordinary type of annual, and has more the aspect of a perennial, the more important feature of note being the great range of colours in the flowers, varying from deep-orange to bright-scarlet. Orange is the prevailing colour, and those flowers of this tone in the centre, shading to yellow, are more common, whilst salmon, cerise, and pink shades occur. The leafage is rather sparse, but the profusion of bloom makes up for this deficiency, whilst the individual flowers are about 1 inch across, and crowded on the spikes, these being nearly a foot in height. Seed may be raised as in the case of other annuals—that is, by sowing seeds in the spring under glass and hardening them off before putting them out in their permanent places in the month of May. A distance of 1 foot each way will suffice.—V. C.

A beautiful Knotweed.—There are many Knotweeds. Perhaps the most peculiar is the common Japan Asparagus or Knotweed, botanically known as Polygonum cuspidatum, which is a wood unless kept under proper control. But the plant I recommend now is of a different type. It is called P. spherostachya, and is as yet rare, although not likely long to remain so. It reminds one of P. bistorta, and has long, narrow, rich-green leaves, whilst the flower-buds are about 2 inches in depth, and deep lustrous crimson. It is in its intense colour that constitutes the great charm of this Himalayan plant. As the flowers are produced freely at the base of the rookery when well established in a fairly light soil and sunny spot.—V. C.

RULES FOR CORRESPONDENTS.

Questions.—Queries and answers are inserted in GARDENING free of charge if correspondents follow the rules here laid down for their guidance. All communications for insertion should be clearly and concisely written on one side of the paper only, and addressed to the Editor of GARDENING, 37, Southampton-street, Covent-garden, London. Letters on business should be sent to the Publishers. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Unanswered queries should be repeated. Correspondents should bear in mind that, as GARDENING has to be sent to press some time in advance of date, they cannot always be replied to in the issue immediately following the receipt of their communication.

Answers (which, with the exception of such as cannot well be classified, will be found in their different departments) should always bear the number and title placed against the query replied to, and our readers will greatly oblige us by advising, as far as their knowledge and observations permit, the correspondents who seek assistance. Conditions, soils, and means vary so infinitely that several answers to the same question may often be very useful, and those who reply would do well to mention the localities in which their experience is gained. Correspondents who refer to articles inserted in GARDENING should mention the number in which they appeared.

4455.—**Climbers**.—What sorts can I get to have an assortment of colours?—LACONOPOLIS.

4456.—**Best Strawberries**.—Will someone kindly tell me the names of the best dessert Strawberries?—ARANT.

4457.—**Gravel road and walk**.—Is there anything to prevent a green sort of slime collecting on a gravel road and walks?—M. B.

4458.—**Striking Ceanothus**.—I wish to know how to strike Ceanothus—whether when leaves are off, like Honey-suckle, or not?—M. A. D.

4459.—**Treatment of a Stephanotis**.—Would someone please state what amount of heat will best suit a Stephanotis?—HELVY OAK.

4460.—**Management of Hollyhocks**.—Will someone kindly tell me something about the general management of Hollyhocks?—A CONSTANT READER.

4461.—**Pollarding Apple-trees, &c.**—What would be the effect on Apple-trees if pollarding them? What is the best remedy for old Apple-trees which have canker?—E. C. H.

4462.—**Creeper for a small greenhouse**.—What would be the best creeper for a small greenhouse heated by hot-water pipes during winter, and feeling south-west?—ARANT.

4463.—**Seed from Tomatoes**.—I should be greatly obliged if someone would tell me the best way of obtaining seed from Tomatoes. Also, should the largest fruits be chosen?—JAWON.

4464.—**Fern seed**.—How long does Fern seed take to germinate? I have no glass, but have sown some in a fern pan, with a sheet of glass over it, and placed in a warm room. Will they come to anything?—A. O.

4465.—**Mountain Ash (Rosa rugosa)**.—Will anyone kindly tell me how to preserve Mountain Ash berries, and the hips of the Rosa rugosa, for decorative purposes to the winter?—M. A. P. S.

4466.—**Laurels and Rhododendrons**.—Is this a good time to trim Laurels and Rhododendrons? Is it not the time to trim a Taxodium now instead of spring? How long should Viburnum cuttings be kept under hand-glass?—M. B.

4467.—**Fuchsias**.—Will "V. C." kindly tell us where we can procure the Duncrobin Bedder for sale, or about the other week? Also would he, or someone else, kindly give the names of one or two dwarf and hardy kinds? I would like to try them next year. I think they would stand the smoke and dust?—LACONOPOLIS.

4468.—**Neglected Asparagus beds**.—Asparagus beds have been much neglected and full of weeds. When is the best time to lift roots in order to clean beds? Shall I manure by digging in or by top-dressing? Can I cut from beds which have been so treated next season?—ARFORD HOUSE, THURLES, IRELAND.

4469.—**Plantation of Raspberries**.—"Subscribers, please advise respecting treatment of plantation of Raspberries, which has been much neglected—viz., what canes to remove, and when? Also about manuring and general care to ensure good crop next season."—SUCCESSION, IRELAND.

4470.—**Arborearias**.—I have on my lawn four very fine Arborearias. They are about 14 feet or 15 feet high on clay subsoil. All the branches to nearly the top of one of these trees is dead this summer. I should like to know the cause of this one getting off in that manner, and the other three trees are throwing out young branches?—ELIAN JELLYE.

4471.—**Wood-sashes**.—Will anyone tell me where to obtain wood-sashes? I have applied in vain to dry-layers, who do not make, and chemists. These sashes are constantly recommended in gardening books, and I find them a most useful paper. After reading it I pass it on to my gardener, marking any article which I desire him to note.—HESON.

4472.—**Scale insects**.—I should be glad to know what I ought to do so a Peach-tree which has been infested by these insects to prevent them from reappearing next year? I have rubbed off all the scales, but I have reason to believe that many grubs are already hatched and hiding in the bark? Would it injure the tree to wash the bark of the branches with paraffin?—B.

4473.—**Lily of the Valley**.—A bed of Lily of the Valley has become smothered with weeds. When is the best time to lift roots for purpose of cleaning bed? I dug in manure, or merely top-dress, and when? If I divide clumps which are very thick, shall I, by so doing, sink the flowers for next year? If I lift the bed with thinning will they flower next season?—ARFORD HOUSE, THURLES, IRELAND.

Drawings for "Gardening".—Readers will kindly remember that we are glad to get specimens of beautiful or rare flowers and good fruits and vegetables for drawing. The drawings so made will be engraved in the best manner, and will appear in due course in GARDENING ILLUSTRATED.

4471.—Propagating a Magnolia.—Will anyone kindly inform me if the Magnolia can be propagated from cuttings, and when should these be taken? I have two Magnolia-trees, one having a south aspect. It is an old tree and bears many flowers; the other is a young tree with an east aspect. This is only the third season it has flowered, and has had two, five, and this year three flowers?—M. E. L.

4472.—A new house.—I shall be moving into a new house, which has been built on a field, the end of next month, and to which is attached a piece of land for garden, about 170 feet by 85 feet, now in grass. I should be glad if anyone would advise me the best way to proceed to get it into order as soon as possible for planting, and also what I could plant with advantage now. Soil rich, garden running north and south.—A. T. D.

4473.—Himantophyllum.—I shall be much obliged by any answers to the following: A plant of Himantophyllum minimum has two offsets, with five leaves on each, full grown, and another offset just starting. Which is best, to leave them on the plant, or to have two pots? I shall not be able to put to heat until cold weather sets in. I have allowed two seed-pods to remain on the parent plant. When ripe, how should they be treated?—W. H. J.

4477.—Making Asparagus-beds.—I am going to make some Asparagus beds if some experienced reader will say if the way will be right I am going to start? My soil after one spad deep is porous. I am going to take out 3 feet deep, cart it straight away, and then start road-scrapping one layer, then salt, then manure, so on until it is finished? Would three-year plants do, and could I start to cut the first year? What time would be the best to start? A few practical hints would greatly oblige.—ANAPROUS LOVER.

4478.—Agapanthus umbellatus albus.—Is it possible to force this lovely thing, as in GARDENING ILLUSTRATED that it was advisable not to water it in the winter, as it died down. I had a blue Agapanthus as well as the white (new plants), and treated them exactly as advised, and when the flowers came out, lo! the labels had been put on the wrong plants, and the white had received the treatment meant for the blue, and with the best results, as there were three splendid heads of bloom on it; the blue did not bloom at all.—W. H. J.

4479.—Planting Rose-beds.—Many persons advise the planting of Roses and other beds with dwarf alpine plants to cover the surface. I want to know how to protect the plants under these circumstances? I have always applied a thick layer of stable-manure to my Rose-beds in winter, and dug it in in spring. Must the carpet plants be removed, or covered with the manure? I should like to carry out the plan with my shrubby borders if possible, but they have to be heavily manured every spring, as the roots of the shrubs exhaust the soil.—MERON.

4480.—Plants for winter.—My garden is now full of bloom, and so beautiful is the effect of the various bedding and other plants, also Roses, now in their glory, that I am dreading the approach of winter, with a consequent disappearance of these lovely floral gems. Will anyone, however, suggest to me the best plants for the garden, kindly say what plants should be put in the beds? I have a succession of flowers through the winter months? Aspect due south, gentle slope, rich earth, well exposed to easterly winds. I may say my Roses have bloomed beautifully this year.—SEMPER FIDELIS.

4481.—Growing Osluyne cristata.—I have two 7-inch pots of the above Orchids that were bought from a nurseryman about two years ago. They have never had one single bloom on yet. I am told it is a easy one to grow. Easy or not easy, I can't grow it; I wish I could! I have got a beautiful one, well heated. I thought it was coming into flower about a week ago, but seems to be late coming out in the base of the flower buds. I am told it will grow on wood. What kind of wood? How should I do it? Would be glad of a little help. Dendrobium I have got don't seem to be doing well.—CONSTANT READER.

4482.—A saddle boiler.—I have bought a second-hand saddle boiler, and I see there has been a 1-inch pipe put in the top. It is intended that it should be for exhausting steam in the event of water getting very hot! There is an open supply tank at the extreme end of piping from boiler 100 feet. Also, we are placing flow-pipe at top of boiler with a gradual rise to supply tank, but the return-pipe branches off with smaller pipes to each side of bottom of boiler, the consequence is an incline of more than 2 feet more than to the flow-pipe. Would it matter if the flow-pipe was perfectly level? In that case there would be 12 inches fall in the 100 feet from supply tank of the return-pipe. My reason is to have a cock-hole as high as I can.—JAMES HARRISON.

4483.—Heating a greenhouse by oil-lamps.—I had a greenhouse built this summer, 3 yards long and 2½ yards wide inside. It is built against a wall. The district is North-west Manchester—the coldest part. I have spoken to several people about heating, and some say that oil-lamps are of no use, and others say that I should find them to answer well for a greenhouse of this size? I should like to have an opinion on the matter, as if oil-lamps, which they will be less expensive than hot-water apparatus, but on the other hand, I want to keep my plants alive during the winter. I intend to plant Roses to grow up the bank wall; they will not grow outside owing to the smoke. What else can I try to grow?—W. HAYES.

4484.—Red and White Lapagerias.—I have a Red and White Lapageria planted out in each end of a passage. The drainage appears to be all right, and the plants are trained onto the roof and along it in galvanised iron wire. At several places where the stem touches the wire brown marks have appeared, and to the case of the white one to such an extent that I am afraid it will die. Had I better cut these shoots back as soon as the flowering is over? They are from 18 feet to 20 feet in length, and the marks begin close to the bottom of the shoot, when it first touches the wire. The red one is not so bad; the white one is more shaded places. But will this plant be in flower in the next year? The plants are now young shoots kept dying back, which is a sad business for me. I shall be very glad if you can give me any advice.

The plants have been planted about six or seven years, and they have had a top-dressing of fresh soil every year.—W. D. S.

4485.—Vine trouble.—I am in trouble concerning my Vines. The house is a lean-to, it is 40 feet long, with outside border 3 feet wide, raised 1 foot, at foot and 18 inches at back. I have in it four Vines about twenty years old, and three about seven years old. My first year, 1890, was a failure. I took to the place too late to do them well. In 1891 I had 75 fair bunches. In 1892, 125 bunches, with a few shankers. Then I followed the advice of GARDENING. In the autumn I took a trench out of the border, 2 feet deep, and filled it in with lime and plaster rubble. In February I gave the border two bushels of bone-dust and a liberal supply of fresh stable-manure, and allowed the Vines-roots to break naturally. I followed up with five, and I rejoiced to see a bunch at almost every side-shoot. In due course I cut out more than a hundred bunches, leaving about four hundred, and all went well up to three weeks ago, when the colouring appeared to stop, and the bunches are now going limp and very indented. I cannot trace any disease and very little shanking. Seven weeks ago I gave the border a dressing of cow-dung, thinking to give support through the ripening stage. Will any of your correspondents help me? I have dumped the house every evening.—ALFARO DAVISO.

4486.—Nasturtium and Tropaeolum.—What is the difference between the two? I would like to know a little more than I do about the habits and treatment of the different kinds? I am living in a very sticky district, and I cannot get anything I have tried yet to stand the smoke and showers of ashes that fall in my back yard, the only place I have to grow a few plants, except the Nasturtium, Stokes, Marigolds, Sweet Peas, "Geranium," &c., will not stand it. The blooms of one and all open and fall off in a very short time, although the plants are vigorous enough. I have Scarlet Runners 18 feet high, and still growing. Great trusses of buds open out at every joint, but fall off to a day. They do not stay on long enough to form a pod. Now, the Nasturtium are splendid, 3 feet or 4 feet high, and covered with blooms, and the leaves are clean and healthy, while all the other things are covered with dirt. I have only four hours' sun a day, from eight to twelve, about an hour longer in June. What I want to know is, what will bloom and stand the dirt as well as the ordinary Nasturtium? Is the Climbing Nasturtium the same thing as the old fall kinds? 3. Please recommend a quick and hardy climber for a window, four hours' sun, north-east aspect, either to plant now or to the spring?—ISOROBOLIS.

To the following queries brief editorial replies are given; but readers are invited to give further answers should they be able to offer additional advice on the various subjects.

4487.—Insect pests (Eight Year Subscriber).—What insects they were you sent I cannot say, for when they arrived they were all reduced to a powder, but all such things should always be kept away. So take my advice, and clear all the things away carefully, and keep them clean and comfortable.—J. J.

4488.—Tree-Ferns (Kitt).—It is quite impossible to place names to these small plants sent to me on the 10th inst. It is quite difficult enough to make out the smaller kinds from such diminutive specimens, and when you give me such a task I must decline it with thanks. You do not give me the slightest size of the plants, or any one thing to form an opinion upon.—J. J.

4489.—Dendrobium thysiflorum.—In reply to an "Eight Year Subscriber," this plant, having finished its growth, should have the water supply stopped, and it may be placed in a cooler house, exposed to the sun and with a good supply of air; but do not keep it so dry that the bulbs or leaves suffer, and if the growths are strong enough, you will be rewarded by the appearance of its large and ornamental pendulous spike of bloom by-and-by.—M. B.

4490.—Epidendrum tovarense (July).—I do not know if I am right about this plant, and I do not remember to have seen it in any collection in this country; but I have seen it in many gardens abroad, but never in flower, so that when you plant it, should be exposed to the sun, or obliged if you will send me one. The plant comes from the mountains of Venezuela, and does best under cool treatment in the summer, but it would appear to want a slightly warmer temperature during the winter months.—M. B.

4491.—Hardy ornamental Ferns (Femist).—In answer to this enquirer, I think the following kinds will suit you admirably. I have carefully avoided small and misty kinds, and these are as distinct from our own native kinds as possible: Arhated virginica, Botrychium lucidoloides, Botrychium virginicum, Lastrea podophylla, Lomaria obliquata, Lomaria arcolata, Onoclea sensibilis, Osmunda cinnamomea, Osmunda Claytoniana, Polystichum acrostichoides, Streptopteris germanica, Struthiopteris pennsylvanica.—J. J.

4492.—Oniscus (woodlice) (C. B.).—I have had several complaints of the ravages committed by these pests, and most persistent in the effort in destructive force to O. asellus, which may be readily distinguished from O. asellus by the last-mentioned rolling up into a ball when disturbed, or when at rest. The writers complaint of the spikes of the Orchids being eaten by them. To prevent them getting up these, cotton wool should be put on the spike quite low down; this prevents them climbing up. They should be washed out of their haunts by the application of strong gas-water, and gas-time should also be laid about their runs. Try pieces of wool and small empty pots for entrapping them.—M. B.

4493.—Catalpa gigas (J. S.).—This is a fine flower which you send. I take it to be the variety Sandbariana, but it is rather a starchy flower, which, however, may improve, and another season the petals may come broader, and thus fill up the space better between the sepals and the petals, making it rounder and a fair flower. The latter flowers always present a better appearance, and are more taking. The colour is all the better for being kept cool, so that it does not start into growth through

the winter, and let me hear from you again next year what it blooms. You may keep it cool and dry after its growth is finished up, but not too dry, or otherwise the buds and leaves will suffer, which must not be allowed.—M. B.

4494.—Epidendrum Frederici Galleitii (July).—This is a plant that comes from the mountains of Peru, at 6,000 feet to 8,000 feet elevation. It was first introduced by Mr. Lindoe some years ago, but more recently it has been introduced by Mr. Shuttleworth, of Clapham, who, however, I think made a mistake in having his plants out down too short; it weakened the old stools and made them break rather weak, but I find them increasing in strength in various places, and if you treat your plant in a rational manner, it will gain strength and flower freely. The flowers are reddish-purple. You should put it in peat-fibre and Sphagnum Moss, drain well, keep the plant well supplied with water, and it will do well with Odontoglossum Alexandro, and others.—M. B.

4495.—Horebills (E. H. Pollard).—The insect sent is not a wasp of any kind, nor does it sting. It is a species of wasp of condition, and does not keep its feet wet. It belongs to the family of Ichneumonidae, and is a very common insect, and it may fairly be said to be a noxious insect, as it will attack horses, cattle, and human beings. Though these flies have no sting, the organs of their mouth are so formed that they can pierce the skin of animals and suck their blood. They are not often found in houses, but I was in church on Sunday morning at Thun, in Switzerland, when a number invaded the church. Many of the congregation left the church, and the remainder kept their heads covered in constant motion, trying to drive them away, during the rest of the service.—O. S. S.

4496.—Dendrobium Wardianum (Eight Year Subscriber).—If this is still growing keep it under the same conditions, and do not keep it too wet, or the eyes at the base of the stems are apt to push, and if they push in the winter, you know you must not expect strong or vigorous growth. Neither must you begin too soon to resort to a resting period for this plant. I have done this plant last year easing the water supply, until it is about entirely stopped. I have then taken them and suspended them in the full sun during the months of September and part of October to an early viney, afterwards putting them in a cool part of the Cattleya-house, where they may remain until the buds begin to show signs of coming, when the plants may be gently brought to fresh life.—M. B.

4497.—Woodwardia radicans (J. Elliot) seems to recommend a fern for a window, and the cool house fernery, and this plant makes a large specimen which is admirably adapted for such a place, for it makes broad and beautifully arched and pendent fronds, and nothing can be more beautiful. They sometimes attain to 6 feet in length, and are of a rich, bright-green colour, being viviparous near the apex. This, planted in a mixture of loam and good leaf-mould, made sandy and well drained, will succeed well and give you a specimen which you may be proud of. It requires a very liberal supply of water in the winter, but it does not like to be recommended much over-head from the syringe, because it has had its fronds turn black with it, and which I have attributed to water from the syringe.—J. J.

4498.—Ornanchae.—T. Kille asks me a question: "If he is to proceed to be enabled to cultivate any number of the Brom-rape family?" I have never seen these plants cultivated, still it is worth a trial, and to succeed with O. moor, which is mostly found growing on the roots of Clover, I would mix some seeds with that of Clover, and sow them together in the border. Any other species which may grow on the roots of any Leguminous shrub or plant may be sown upon the roots of these plants to the open border. I know of no other plan in which to proceed with these things. You must first get the plants of the Ornanchae like to grow upon, and get seeds of the Ornanchae and sow it upon the roots, and I should not imagine there is much difficulty in the matter. If it should succeed we may get have plants of the famous Rafinesque grown in our stores, which would, indeed, be a great achievement.—J. J.

4499.—Potting Odontoglossums (C. Darling).—You are like a great many more people, first do a thing and then ask advice upon the subject? You say your plants "were potted last month, but they do not seem to move a bit." Well, now, there are two reasons for potting at this time; one is, if the plants are in a bad state, and another reason is, in the event of having plants coming home in the season you came, and in the last-named case I would advise the plants to be placed upon some crocks, and kept very cool and moist, but in the case of the others, they should be potted in well-drained pots, and a little soil placed about them; but if you have deliberately been shifting them in the month of July, and because they do not appear to be progressing, I have little doubt that you can see them decreasing, and you should have asked advice first. I consider the very best time to repot these plants is in the late autumn time, so that the plants may grow and establish themselves in the winter, and then you can then maintain themselves in good order throughout the hot weather, but during the summer season they must not be touched.—M. B.

NAMES OF PLANTS AND FRUITS.

*. Any communications respecting plants or fruits sent to name should always accompany the parcel, which should be addressed to the Editor of GARDENING ILLUSTRATED, 37, Southampton-street, Strand, London, W.C.

Names of plants.—G. B.—1, Peris scaberula, wants plenty of water and shade; 2, Phlebodium aureum; 3, apparently a Blechnum, send again when fertile; 4, Onychanthus lendigeri; 5, Cyrtanthum falcatum; 6, Onyohium japonicum.—G. H.—We cannot name Ferns from such small pieces, especially when infertile; in sending again send a reasonable number at one time, not as now, twenty-four.—Thos. Green.—The wild Teasel (Dipsacus sylvestris).—W. H. W.—The red net Fern (Nidula). It may be distinguished by its sharp knob rib at the back of the frond.—B. W. B.—1, Onoclea Forbesi; 2, Onoclea Linnæusum.—C. Fuller.—1, Scopolopodium vulgare, typical fern; 2, some crested variety, but it always like this it does not deserve a name; 3, Applenium

G. HAYWARD F.R.S.

CRYSTAL PALACE HORTICULTURAL WORKS,
80, FOXBERRY ROAD BROCKLEY, LONDON.

This is Hayward's No. 1 and No. 2

No. 1 Span-roof and No. 2 Lean-to Greenhouses are prepared especially for amateurs, made of Best Red Deal, thoroughly seasoned, complete with Ventilators, Door, Stages for plants, Painted one coat, 10-oz. Glass, all necessary Iron-work. Delivered and packed free on rails at the following prices, satisfaction guaranteed. Write for New List.

Ten minutes by L.C. & D. Railway from City and West End. WORKS CLOSE TO STATION.

THE LARGEST MANUFACTURERS OF RUSTIC SUMMER HOUSES & RUSTIC WORK IN ENGLAND.

Large stock always on hand from £3 10s. upwards, carriage paid, or delivered and fixed in London and suburbs. INSPECTION INVITED. Send for New Catalogue, 72 pages, 3 stamps. Orders by post punctually attended to. These Houses can be fixed in half an hour.

AUTOMATIC DAMPER FOR GREENHOUSE BOILERS

See it in operation at Royal Horticultural Socy. Exhibition, Agricultural Hall. PATENT AUTOMATIC DAMPER CO., 97, FLEET STREET, E.C.

PEDIGREE SUSSEX CATTLE (Gravetye Herd).

The Sussex cattle are growing steadily in public favour, both in this country and in America, where a few years ago a steer of this breed won the first honors at the stock test at Chicago. Choice Cow and Young Steer of the best blood for sale. This herd never gets up for show, but kept under the most natural conditions possible. Inspection invited.—Address, BAILIFF, Some Farm, Gravetye Manor, East Grinstead, Sussex.

TRELLIS TRELLIS

Superior planed extending
The new ornamental half-round
Cheap and durable
For all training purposes
For tennis-courts
For foot runs
For garden bordering
For the fruit and flower garden
For unsightly corners

The Trellis, as herein advertised, having been found to be both durable, useful, and ornamental, fulfilling all the duties required, as in large demand, and being inexpensive, should be adopted as necessary for all the separate purposes above expressed. To be had of the principal Ironmongers. If any difficulty in obtaining it, please apply for the name of nearest Agent.

ROSES.

POT-ROSES.

SEPTEMBER is a very important period in the management of these, and unless properly attended to now first-class results cannot be obtained. For the past six weeks or more all pot-Roses should have been out-of-doors. Those of my own that were placed out-of-doors at the end of June I bring under cover again in September. These plants have then attained to a certain degree of ripeness, and then broken into more young growth. My object in housing the most forward of this first batch is to make certain of securing a lot of clean blooms late in the autumn—a time when wet and stormy weather often makes them invaluable as cut-flowers. As a rule, however, I should not advise them to be housed quite so soon, unless in the case of those who, like myself, have to keep a supply of out-Roses all the year round. What I do strongly recommend at this time of year is to turn the plants round a few times, very slightly loosen the surface soil, and out away all weak and spindly growths that too frequently come in the form of blighted or flowerless laterals. By timely removal of these you will admit much more light and air among the sounder and more valuable wood. It is also so much easier to see whether the drainage is sound and to afford additional water to a few plants that may be over-dry during the operation of turning round and trimming out the plants. It does not take long to pass several plants through one's hands, and the amount of good done by an occasional run through in this way is far more important than many suppose. There are few more important months than September and October—sometimes so hot and fine, at others so boisterous and wet. In the case of dry weather it will be doubly necessary to give due

ATTENTION TO WATERING, because among the pot-plants set out early, and especially those of the Tea-scented class, young growth, with its consequent root-action, will have commenced. It is when such plants are allowed to get dry at the roots during the middle and end of October that so much of the young growth receives a check and comes blind and flowerless. Again, so very much depends upon the time of year at which you may want the bulk of your blooms to be in perfection. If not until March or April, it will be wise to place the plants into a deep pit or frame, so that heavy autumn rains may be kept from them. I do not advise they should have the lights placed over them excepting during very wet weather. By keeping the soil on the dry side without parching you retard the growth, and at the same time bring it to an even greater degree of ripeness. This month is also an excellent time to commence the culture of pot-Roses both among the Tea-scented and Hybrid Perpetual classes. In the case of the former, I would strongly recommend that young plants of this season's working be chosen. These can now be purchased in what are styled "trade" pots—those long or deeply-made pots which hold a

little less soil than the ordinary 6 inch sizes. Such Roses will be fairly well ripened before leaving the nursery, and if a little more care be taken in the way of securing a few weeks in the open air and a fairly dry soil, they may be safely forced the first season, and will generally produce a fair amount of bloom. As these small pot-Roses may be bought at about the same price as strong plants from the open ground later on, and will give a far better return the first season, they are undoubtedly the most serviceable for pot culture. There is no need for a large amount of wood upon such useful Teas as Rubens, Catherine Mermet, Mme. Faloot, Souvenir de S. A. Prince, The Bride, &c., the only desideratum being that all of it shall be efficiently ripened. Such plants will also grow on to be really grand and useful subjects by next year, and are likely to turn out more satisfactory than those potted up from the open ground, and which were probably not much more than half or three-parts ripened, and also minus of many of their fibrous and valuable roots, a case that cannot well happen to those always kept in pots. The

HYBRID PERPETUAL CLASS may be taken in hand during the present and following month. Many varieties that are on the Manetti-stock are already almost bare of foliage, and are quite ripe enough for potting up. I am on the point of commencing this work among my own Roses, and shall not hesitate to move any that have commenced to drop their lower leaves and are not breaking into the weak and late lateral growths these early-ripened plants are apt to do before or at winter is upon us come more. By lifting and potting these thus early one avoids the puny and useless growth, and the eyes that would otherwise produce these are checked in their precocity and induced to ripen up into really useful wood. The potting of these has also been dwelt upon at considerable length, and I will only warn readers against standing such newly-lifted plants in a sunny or windy position. Choose a shady place, and take care that the plants are frequently and thoroughly syringed overhead during fine weather. This will prevent the wood from shrivelling and will retain all the sap in the plant. Early potted Roses, too, especially those on the Manetti-stock, will commence root-action and become more than half established before winter sets in. You can force such plants the first year, and although they will not stand such severe forcing as those established the previous season, nor as the small pot Teas before noted, they will be far more satisfactory than plants lifted later on, provided you secure their wood from shrivelling in the dry autumn air we are sometimes favoured with. Of course, the more quickly they can be potted after lifting the better it will be. In purchasing Roses for this purpose, be sure they are on the Manetti-stock, as plants on this will be much ripier than the same variety if growing upon the seedling or cutting Brier. R.

4435.—Culture of Roses for exhibition.—You say you have been successful at local shows and want to fly at higher game. You have 250 plants in almost as many varieties, and now propose to add six Teas and the

same number of H. Perpetuals, three of a sort. In query 4433, you ask the names of two dozen good varieties of H.P.'s? I would advise the cutting out of a few of your worst Roses and replacing with such of those named that you do not already possess. This, with the others you intend planting, ought to be sufficient to allow of your showing twelve fairly good blooms. But so much depends upon whether the majority of your plants are "in cut," as exhibitors style it, or not. You would do well to keep your stock below one of the numbers mentioned in the National Rose Society's schedules, as by doing this you meet men of your own calibre when competing at most good Rose shows. Of course, the more plants you possess of suitable varieties the better chance you have of finding a good bloom at the time when wanted. The twelve Teas you name would be greatly improved by replacing the following: Madame Lombard, Amazon, and Madame Charles, with Souvenir d'Elise Vardon, Innocent's Pique, and The Bride. Teas do not require quite such hard pruning as the H. Perpetuals, and will generally produce a few good growths if only out-hack in the partial manner you describe.—P. U.

4433.—Manures for Roses.—"A Rose in June" asks which are the best manures for Roses, and then goes on to describe half-a-dozen kinds which he uses. He could not possibly do better than continue the same, but I fear he is overdoing it in mulching so heavily twice a year. Lime is most beneficial when used occasionally upon ground that has become too rich in humus from over-maturing; I would not recommend it in any other case. Disbudding is certainly of great service in securing larger blooms, but you must do it immediately the side buds are large enough to handle. You ask for twenty-four best Roses (H.P.'s) for exhibition. The following are what I would select, although hardly two growers would give exactly the same sorts: A. K. Williams, Alfred Colomb, Camille Bernardin, Charles Lefebvre, Comtesse d'Orford, Earl of Duffryn, Francis Michellon, Gustave Piganteau, Horace Vernet, Louise Van Houtte, Gabrielle Luizet, Marie Beaumann, Maries Bernardin, Mrs. John Laing, Prince Arthur, Suzanne Marie Rodonnaohi, Victor Hugo, Ulrich Brunner, Prince G. de Rohan, La France, Viscountess Folkestone, Caroline Testout, Marie Verdier, and Duke of Edinburgh.—P. U.

4432.—Rose W. A. Richardson — if you let your plant of this grand variety grow at will, and cease to mature so highly, I have no doubt the defect you mention will be considerably, if not entirely, diminished. This Rose almost always bursts open in full sunshine; in this respect it is similar to most varieties that are scarcely more than semi-double, and the present hot summer has affected them very much.—P. U.

4410.—Roses for north border.—Almost all of the varieties named in a good catalogue, except those specified as being of moderate or tender growth, will do fairly well in the north, and also upon a north border in the south and middle of it, if, however, name

a dozen good varieties of distinct colour; but this list might easily be extended to a hundred. General Jacquemint (red), Prince C. de Rohan (maroon), Charles Lefebvre (velvety-red), Dupuy Jamin (cherry-red), Baroness Rothschild (pink), Mrs. John Laing (soft lilac-rose), Souvenir de S. A. Prince (white), Marie Van Houtte (yellow), Safrano (apricot) Francisco Kruger (orange-buff), Jean Dacher (salmon), and Edith Gifford (cream).—P. U.

4423.—**Roses against a wall.**—I would advise you allowing the strong shoots of your Gloire de Dijon to grow as freely as possible until matured. Then in the spring you can lay in as much of the new wood as your wall can accommodate and remove the remainder. If you check the growths now the probability is they will break into useless laterals; whereas if left until spring each matured eye will produce a grand cluster of blooms.—P. U.

4416.—**Tea Roses.**—You ask for a few names of large-flowering Tea Roses, and mention three varieties as examples. Neither L'Idéal nor Grace Darling can come under the title of large Roses. Here are a few: Perle de Jardine, Sunset, Souvenir d'Elise Vardon, Innocenté Pirela, Belle Lyonnaise, Madame Hoste, Anna Ollivier, Maréchal Niel, Ernest Metz, and Devoniania.—P. U.

4424.—**Budding Roses.**—It is somewhat difficult to describe the proper stage of growth a Rosebud should be in. You may take it that when the wood is about three-parts ripened, and the bud is plump and prominent without actually being in new growth, that the bud is suitable for propagation. Another point which will guide you somewhat is to observe whether the seat or heel of the bud is left intact when the small portion of wood has been removed from beneath it. If the bud was too forward the seat will be left upon the piece of wood removed. It does not matter what stage the bud may be in so long as this root or seat is perfect and prominent enough to rest upon the wood of your stock. The latter part of your query, referring to covering the buds with soil or not, is easier answered. If you plant the stocks as shallow as possible, and then earth them up the same as Potatoes, when you remove the soil for budding the bark of the stock will be in a much better condition for working. Do not return the soil. Light must reach the bud to a certain extent, and a much more perfect union will be made under the partial shade afforded by the stocks. Next spring, when the young Rose commences growth, earthing-up is again very beneficial, but not before.—P. U.

4197.—**Planting Rose-beds.**—I have seen beds covered with different Sedums, &c., but do not recommend them myself. The best plan would be to lift the surface plants in the autumn, propagate from them, and keep in a frame until spring, when they may be replanted. In the meantime any mulching and turning over can be accomplished. The benefits derived from covering the surface with these subjects are: First, the better appearance during summer; second, freedom from dirt splashes during heavy rains; and, thirdly, a cooler and moister soil for surface-roots of Roses.—P. U.

4484.—**Red and White Lapagerias.**—Keep the stem away from the wire by either crossing the tie between them or wrapping a bit of cloth round the wire first. The wire is probably galvanised, which accounts for the injury. What kind of soil are the plants growing in? They thrive best in a mixture of peat, leaf-mould, sand, rough grit (such as bricks broken up rather small), and some lumps of heavy loam. They require more water than almost anything else, and should have a large can or pailful each daily such weather as this.—B. C. R.

4471.—**Wood-ashes.**—In country places wood-ashes are generally made at home by laying on one side all prunings of trees and shrubs, and another-burning the heap as often as is necessary to make clearance. Hedge and shrub prunings with all fibrous matters, such as Artichokes and Asparagus stems, are placed on the heap after the fire is started, and the whole smothered down when the fire attempts to break through with coarse weeds, &c. This will not be altogether pure wood-ashes, but the vegetable matter will not extract much from the soil.—G. H.

GARDEN WORK.

Conservatory.

Discontinue picking flower-buds from Zonal Palargoniums, and take leave before there is any danger of frost. Begonias and other water-flowering stuff, which require heat to open the flowers, should be moved from cold pits to a house where heat can be given when necessary. Poinsettias and Euphorbias will be better with a little warmth at night. New Cinerarias, Primulas, and Cyclamens are quite safe in cold frames for the present. Do not keep the plants too close, or the foliage will draw up weak and flabby; the more air the plants have the better. To obtain very large plants thift some of the strongest Cinerarias into 7-inch pots. Late-sown plants will now be ready for thinning into 5-inch or 6-inch pots. Good specimens of *Abelia floribunda* are very effective now; this plant is very easily grown, and rapidly makes a good specimen. There are several hardy or nearly hardy plants which come in very useful to give variety in the conservatory now. Among these are *Campylopus pyramidalis*, blue and white; when well grown, these are very effective. *Campylopus leucophylla*, white and blue, are charming things for flowering baskets. *Trochilium coruleum* makes a nice specimen, and the flowers, which are blue, are produced freely. These are useful plants for the unheated greenhouse. Get the Dutch and other bolts for early forcing potted without delay. *Camellias* and *Arasias* must be taken indoors, but the house should be kept quite cool, and have ventilation night and day, so that the plants, after being housed, may be gradually inured to the change. When such plants are kept outside to the last moment, and are then taken to a house where artificial heat is used in even the smallest measure, the foliage will suffer from the change. The early-struck *Bouvardias* will now be fit to place in 5-inch pots; young stuff of last year out back will now be coming into flower, and when mixed with rather small plants of Maiden-hair Ferns the effect is charming in a good-sized group. Good plants of the new variety *Furly* and *Montana* are particularly attractive now. Still potted *Tuberose* which have been grown in the greenhouse will now form a nice oblate group in a groundwork of Ferns. *Tuberose* flowers are as valuable in the autumn as at other times, and they are not much trouble. Pot in April, and keep them moving on slowly, with just a little warmth to finish them.

Stove.

How beautiful the different forms of *Aparagus plumosus* are when planted out! This is the only way of getting long wreaths for cutting. They will thrive in any good soil which is well drained. Very old plants may be cut down and the roots divided to make stock. Seeds are sometimes produced, but as usual good seeds are scarce. Plants which are usually grown in this house must be brought back from cold houses. Some of the least valuable will have to be thrown out, as room for young specimens comes on. Still continue as opportunity offers to reduce climbers to make room for winter-flowering subjects. *Pestilosa procera*, *Ipomoea florulentum*, and *Jasminum gracillimum* are all useful things for flowering in winter. *Allamanda* and *Dipladenia* are still effective. *Pergularia odoratissima* is a beautiful climber for a large stove; the flowers, which are borne in large clusters, have a powerful fragrance distinct from all other flowers. A little extra water will be thrown out, as the soil sufficient must be given to moisten all the soil when watering becomes necessary. In the hot weather very little disinfection was required; now some judicious use is necessary, as some plants will not require watering every day, or perhaps in dull weather not oftener than twice a week. Then, again, some things will shortly be going to rest. *Amaryllis*, *Gloxinia*, and *Achimenes* are approaching the end and yellow leaf, but to compensate we have *Ceseris* in variety, which if well done are charming things in a small moderate-sized stove. *Gardenias* will soon be making a move now. See that Mealy-bug is kept down.

Shrubs and Plants for forcing.

If three have to be purchased orders should be sent in at once. Among the most useful things are *Lilacs*, *Asias Mollis*, *Indian Arasias* (especially *Deutscher Baum*, which forces well), *Berula gracilis*, *Fayalae*, *peculiata*, *Rhododendron*, *Kaimia*, *Syringa*, *Spiraea japonica*, *Delytra spectabilis*, *Solomon's Seal*, *Lily of the Valley*, *Honeysuckles*, *Roses* in variety, *Weligia rosea*, *Laurentina*, and *Jasminum nudiflorum*, &c. It is very important that all trees and shrubs for forcing should have undergone a course of preparation. Things which have been established in pots for a short time feel less check, and the buds are, as a rule, better matured than plants lifted straight from the ground. Some things—*Rhododendron*, *Syringa*, and *Delytra*—do very well when lifted straight from the open ground and placed in pots; and I have forced *Lilacs* which have been taken straight from the border to the house, although the forcing in such cases would be gradual, not rushed along in a strong heat from the first.

Orchard-house.

As the fruit is gathered remove the trees to the open air. If any of the trees are to be kept in a shed they may be given at once into pots two sizes larger, the soil to be rammed in quite firm. Shelter the pots before frost comes with long litter, and let them be stood either on a thick bed of coal-ashes or on bricks or planks to keep out worms. Fruit-trees must not be allowed to get dust-dry at any time.

Melons and Cucumbers in frames.

Everything possible should be done now to keep up root warmth. Mounds of warm manure placed round the sides of the bed will be a great help; these ridges may be 2½ feet wide, and should reach nearly up to the top of the frame when pressed down firmly. The growth must then be kept thin, and the stopping of all young shoots on joint beyond the fruit is very important to stimulating fruiting. When Cucumbers are allowed to run on unstoppped they will run themselves out and cease to bear.

Window Gardening.

Do not water so freely now, and never leave water in vases or saucers. In the management of window plants

* In cold or northern districts the operations referred to under "Garden Work" may be done from ten days to a fortnight later than is here indicated, with equally good results.

the main point of all others which is incumbent on all to grasp is watering. Irregular sowing with the water-pot must kill. When a plant in a pot is kept too wet or too dry for only a few days mischief, which in some cases irreparable, is done. It is true that in winter the chills danger lies in giving too much, but the other extreme must be avoided.

Outdoor Garden.

The preparation or fitting the soil for the crop is of the very highest importance, and when a failure occurs a full enquiry would generally disclose the fact that the ground had not been properly prepared or cultivated. The same remarks apply to the sowing of Roses, Pines, and many other families of exceedingly interesting plants; and the preparation of the soil by tending planters should now be in progress. Roses will be dearer this year. Thousands of Standard Briars have died through the drought, and the growth made has generally been scanty and weak, except in the best soils. For all Roses, except Teas, clay or marl to the land, either naturally or conveyed there during the tending process, will be found of great assistance. A good deep light soil may be much improved by heavy dressing, say 3 inches deep of clay being placed on the surface, and left there for a time, and then lightly forked in. The stratum of stirred or cultivated soil can never be too deep. Usually this stratum of worked soil on the surface is too thin to obtain the best result. To keep a garden tidy at this season involves a good deal of labour. Grass and weeds grow very rapidly, and the less such work is kept well in hand, things will soon come to a dead lock. There are not too many flowering trees or shrubs at this season, and these, in consequence of the heat and drought, have come earlier than usual. The Venetian Sumach, the Buck's-eye-tree (*Pavia macrobotrya*), *Menodora macrantha*, and the different varieties of the shrubby *Hibiscus* (*Althaea frutescens*), are so good that no garden is well furnished without one or more specimens. There are plenty of hardy flowers to brighten the garden in the autumn. The *Galliardia*, the *Rudbeckia*, the *Asters*, *Fyrathrum uliginosum*, *Helianthus*, and Japanese *Anemone* should be grown in masses.

Fruit Garden.

Vines in bad condition from ground to sour, undrained borders, may have the roots carefully taken out of the bad stuff, wrapped carefully up in mats, and have new borders well made to receive them as soon as the Grapes are all picked. Vines wherever possible, always be planted inside, and in cases where there are inside and outside borders, when the roots are lifted only one set of borders should be operated on at once, if any Grapes are required the next season. Thus, if the inside borders are re-made now, wait till roots have got a good hold of the soil before interfering with the outside. Sometimes, when the Vines are in a bad condition, it may be advisable to sacrifice a crop, and do the whole thing thoroughly at once, and when this is done, some of the old roots may be cut out, making room for young wood. The Patent *Silicula* kind is excellent for mixing with the soil where old Vines are being renovated. Bones in any form are also valuable. When the roots of Vines are lifted whilst the foliage is still green the house should be shaded in bright weather, and the atmosphere inside kept damp to keep the leaves in a fresh condition. This has much influence upon the success of early autumn lifting. Pines will soon require to be gone through and the old roots may be cut out, making room for young wood. The Patent *Silicula* kind is excellent for mixing with the soil where old Vines are being renovated. Bones in any form are also valuable. When the roots of Vines are lifted whilst the foliage is still green the house should be shaded in bright weather, and the atmosphere inside kept damp to keep the leaves in a fresh condition. This has much influence upon the success of early autumn lifting. Pines will soon require to be gone through and the old roots may be cut out, making room for young wood. The Patent *Silicula* kind is excellent for mixing with the soil where old Vines are being renovated. Bones in any form are also valuable. When the roots of Vines are lifted whilst the foliage is still green the house should be shaded in bright weather, and the atmosphere inside kept damp to keep the leaves in a fresh condition. This has much influence upon the success of early autumn lifting. Pines will soon require to be gone through and the old roots may be cut out, making room for young wood. enough with fair treatment in the smoky atmosphere of large towns, yet under such conditions they do not flower with nearly the same freedom as those receiving the advantage of pure air and free light of a country spot. Still, it is quite possible to induce strong examples to bloom fairly well in even the most unfavourable localities, the secret of doing so being to treat the plants early in the spring, encourage a free growth under glass during the summer months, and then ripen the buds and foliage thoroughly by exposing them to the full sun and free air in a sheltered spot out-of-doors during August, keeping them at the same time moderately short of water. At all other times the supply of moisture should be liberal, and even during the winter the soil ought seldom to become really dry, the plants being of an avaricious nature. Under this treatment this Lily seldom fails to bloom well; the best soil is a sound, sandy loam, mixed with a third of leaf-mould, and made firm. Drain the pots well and take care not to overpot them. The hybrid *Strapocarpus* is a wonderfully continuous flowering subject, and a nice batch is very useful in the conservatory now. Some of mine have been in flower since May, and are now pushing up the bloom-stems and buds more thickly than ever. They are surface-rooting plants, and seem to thrive best in shallow, wide-mouthed pots or pans, a third or half full of drainage, than in deep pots full of soil. The best should be of a very light, loamy, or preferably peaty character, with a little leaf-mould and plenty of sand incorporated. Shade from hot sun is indispensable. *Chrysanthemums* out-of-doors must be watered freely now, or the foliage will be scanty and the flowers small. Those growing against snowy walls—a situation which suits them admirably, and whence really fine flowers of even the large late kinds are often obtained—must be heavily syringed as well as abundantly supplied with water and liquid-manure, or they will fall a prey to red-spider and thrips, especially in such weather as this. Heavily lilies of all kinds should be planted, divided, or potted at once; *L. candidum*, *L. nigricum*,

of the very best quality must cultivate and nourish the roots of the trees, and to do this efficiently they must be kept near the surface. Planted a second hour of Cucumbers. The plants will not be allowed to bear till they are very strong. With winter Cucumbers the most difficult time is from the first of January till the end of February. This is the time when the plants which have been allowed to bear heavily usually show signs of distress, and not infrequently go off. The reason from dull, dark days to increased daylight is usually too much for them, hence the wisdom of taking only a light crop through the autumn from plants required to bear in March and April. Shifted on last sown batch of *Cucurbitas* and *Primulas*, and a lot of seedling Ferns, which were getting pot-bound in 3 1/2 inch pots have been shifted into 5 inch pots. These will make useful stuff for any purpose, or may be grown on to a larger size.

INDOOR PLANTS.

HYBRID GREENHOUSE RHODODENDRONS.

There are few more delightful flowering shrubs for the embellishment of the warm greenhouse throughout the winter than the various kinds of Hybrid Rhododendrons raised by intercrossing *R. jasminiflorum*, *R. javanicum*, and similar species. The mode of propagating best suited to these hybrid sorts is grafting on such of the seedling varieties as possess a free, vigorous constitution. The stocks require to be raised from shoot cuttings in the ordinary way,

tinged with pink, fragrant), Princess Royal (rose-colour), Prince of Wales (orange-red), Purity (pure white, very fragrant), Roxy Gem (white, pink, and rose), Taylori (pink), Thomsoni (scarlet), Veitchianum (yellow and white). B.

4482—A Saddle boiler.—Yes, the 1-inch pipe was placed where you find it for the purpose you mention; but I have never found these exhaust pipes necessary, and not many engineers see them for horticultural heating. With regard to the flow pipes, I am afraid that if you place them on a dead level for a distance of 100 feet the circulation will be sluggish. With a rise of 2 inches in the distance you mention you will be quite safe. There is no help for the inoline in the return pipes you mention in a Saddle boiler. The depth of the stove-hole depends on the height of the flow pipe as it enters the house. If it has not to enter under the door you can bring it up to any height you like. It is quite right to place the open tank or feed cistern at the extreme end of the pipes when there is not room for it over the boiler. In the latter case the cistern should be connected with the return pipe.—J. C. C.

—The 1-inch pipe in the crown of the boiler might have been intended for one of several objects. It may have been inserted as a separate flow to heat an extra frame or small pit, a propagating-bed, or something of the kind. At the same time, what is called a "stand-pipe" is sometimes inserted in the boiler, but more generally on the flow-pipe, to carry off any air or steam that may congregate, and prevent the apparatus "jumping" or "kicking." If there is a rise of a clear foot or more from the top of boiler into the flow-pipes, these may be on the level; but it is better to give them a slight upward gradient, if only 6 inches in the 10 feet, as on a dead level the air will sometimes "hege" and check the circulation. The return having a greater lucius than the flow is all right, and will not make any difference; it may be either gradual or the heating part may be kept parallel with the flow and the levels be adjusted in the connections.—B. C. R.

4450.—Treatment of a Stephanotis.—During growth the plant requires stove treatment, with a night temperature of not less than 60 degs. to 65 degs. In winter keep drier and cooler, to rest and ripen the growth. If the temperature drops to 50 degs., with the roots comparatively dry, no harm will be done. The Stephanotis should not be altogether dried off, and if it is to do well, keep it free from insects, especially mealy-hug.—E. H.

—Grew in turfy loam, not broken up too fine, or else a mixture of foam, peat, and leaf-soil. A warm greenhouse temperature will suit it very well, but it is best to give a temperature of at least 65 degs. to 75 degs. More will not hurt while growing. When growth seems at a standstill, let the temperature fall for a month or so, as this will conduce to much freer blooming. As soon as the eyes push out again return to the higher temperature.—P. U.

—To grow this charming climber really well it must have abundance of heat and moisture. A temperature of 60 degs. during the winter, with a rise of 10 degs. by night during the summer, and an advance of 10 degs. more during the day, will enable anyone to have abundance of blooms if the atmosphere of the house is kept moist and the roots freely supplied with tepid water, with an occasional dose of liquid-manure, say weakly. Stephanotis does not require a deep border, but it must have ample drainage, anything like stagnation about the roots being fatal to its health. A compost of half fibry peat and loam, with sand and charcoal added to make the whole porous, is what is required for the roots; stimulative matter can be added as a top-dressing. A mulching of horse-manure, to which is added a small quantity of bone-meal, about one part of the latter to ten of the former, will stimulate the plant when growth is most active in the early summer months. Stephanotis is much subject to attacks of mealy-hug; the best remedy for this insect is clean water applied with force through a syringe morning and evening. Mealy-hug can not withstand this daily interference. An open space at the back of the plant-stove, fernery, or conservatory, where it will not be obstructed from the light by other plants, should

Greenhouse Rhododendron "Lady Alice Fitzwilliam."

L. aurantiacum, *L. Martagon*, and several others thrive and flower freely in stove gardens, however smoky. B. C. R.

THE COMING WEEK'S WORK.

Extracts from a garden diary from September 9th to September 16th.

Seed sowing is pretty well over for the season, so far, at least, as regards open-air work. I have just made the last sowing of Lettuce, and the plants will remain in the seed-bed all the winter. If the plants come up thick some will be thinned out. This late sowing always comes in useful. As soon as the Tomato-houses are cleared out one or more will be planted with Lettuces. These houses have not yet been basted, and Lettuces are always a success, and they come in at a time when good Lettuces are scarce. It is impossible to get really good Lettuces early in spring without glass of some kind. Frames do very well, and so do cloches or hand-glasses, but a good roomy house, when it can be spared, produces very good Lettuces in March and April. Buy making up Mushroom-beds in house. Several beds are made up now and spawned as soon as ready. To some extent a successional character may be given by delaying the sowing for two or three weeks. The beds made up now in buildings, if put together properly, will continue bearing the greater part of the winter. The advantage of having a building large enough to hold from six to a dozen good-sized beds consists in the general warmth which is given off by the heaps of warm manure, and which, in a large building, can be kept up by making new beds at intervals of a month or so. Weeds have given us a good deal of trouble, but by bandweeding when the land was damp, and hoeing when the weather was fine, the land is getting pretty clear again. Just overhauled the early seed Potatoes; picked out those suitable for seeds and placed them, grown upwards, in shallow trays or boxes. Will be kept in a light place where the frost cannot reach them. Gathered Apples and Pears. The late fruits are being carefully sorted, and the best samples packed in barrels or boxes. They will be stored in a cool, dark room till the time approaches for using them. The wall-trees have just been looked over to do any shortening or thinning which may be necessary. Several young trees have had their roots lifted partially, and I think sufficient check has been given to bring them into bearing in due season. A great many Apples on the Broad-leaved Paradise variety have been picked within the last half dozen years, and numbers of the old pyramids of the Crab grabbed up. Whoever wants fruit

end grown on in 6-inch or 8-inch pots until large enough for grafting, when they must be headed down to within 5 inches or 6 inches of the pots, and the grafts, which should consist of pieces of the preceding year's shoots, inserted. The work ought to be done in the winter, and after grafting the plants should be placed in sufficient warmth to start them into growth; when some progress has been made the points of the shoots must be pinched out to induce the lower eyes to break, so as to furnish the plants with side branches. After this the treatment is simple, merely giving pot-room as required. These Rhododendrons do not want so much root space as many things, and a good compost for them is a mixture of good turfy peat, with some silver-sand, and the pots should be drained well. It will be well to keep the plants altogether under glass for two years, giving ordinary greenhouse treatment. After the grafts have got a good start in the warmth already advised this is requisite to get them on in size. Afterwards they will be better out-of-doors in the summer. Hybrid Rhododendrons are not much subject to the attacks of insects, but grown under glass they frequently get affected with scale or mealy-hug, for which syringes freely with water, and sponge with soap and water. The under-mentioned are very desirable sorts to grow; Countess of Heddington (blush-white), Countess of Sefton (white and rose), Dennisoni (white and lemon, very fragrant), Duchess of Edinburgh (bright orange-scarlet), Duchess of Sutherland (white, flowers fringed), Duchess of Teck (yellow, tinted with scarlet and rose), Lady Alice Fitzwilliam (figured), large flower, pure white, one of the best), Lady Skelmersdale (pure white), Maiden's Blush (blush-white), Mrs. Kelly (white and pink), Princess Mary and Prince of Wales (pure wax-white), Princess Alice (white,

grow this plant well; but it must have its leaves close up to the glass and receive some shade during the hottest part of the day. During June and July this is best applied from the outside.—S. P.

4476.—*Himentophyllum*.—As there is no heated house at present, it will be better to allow the effects to remain on the plant until the spring; but many growers would rather let

Flowers of Romneya Coulteri.

them remain so as to obtain a large flowering-plant. I have a specimen which has had no effects removed from it for fifteen years. The plants ought to be removed with some roots attached when they are of large size. Seeds may be removed when the pods are ripe. Let the pods remain on the plant for a month or more after they become of a scarlet colour, when they may be removed and the seeds extracted. Sow them at once in bottom-heat in a hot-house.—J. D. E.

4462.—*Creepers for a small greenhouse*.—A Rose, such as *Marshall Niel* or *Niphates*, would do well. A *Passion-flower* (*Constance Elliot*) would be pretty and interesting. *Clematis indivisa lobata* is pretty in spring. Then, to come to commoner things, *Stem. Crouse Ivy-leaf* "*Geranium*," *Hedera*, and *Fuchsia* in variety will all do good work in a small house.—E. H.

I think the *Lapagerias* would give as much pleasure as any else. They are not too rampant, and may be well accommodated within a comparatively small space, whilst they continue to bloom over a long season. There are two kinds—*alba* and *rosea*. The former has pure white flowers, quite waxy in appearance, and produced in long, graceful shoots, whilst those of *rosea* are rose coloured. There is much difference, however, in the shade in varieties, some paler than others, and some larger in size. You must prepare a thoroughly well-drained bed for them, putting in plenty of cracks, and use a peaty soil. The plants are not so expensive now, the dealer of the two being *alba*. In a small greenhouse one does not want a creeper that overhangs every other plant.—G. T.

There is nothing which gives more general satisfaction than *Pumbococcyenia*. It is a creeper of easy culture, and the flowers are the arably admired. If, however, you wish for a creeper which will bloom throughout the year, *Abutilon* is the elegant will suit you.—A. G. BUTLER.

4483.—*Heating a greenhouse by oil-lamps*.—One or two of the small oil-stoves, now so common and cheap, would excite frost from a structure of the size named, and just keep any ordinary greenhouse plants alive, and anything beyond this it is better not to attempt without the aid of hot-water pipes. Keep the stoves clean and well trimmed, use the best oil, light the stoves only when really necessary, and ventilate freely, and the plants will do fairly well, but you must not expect many to thrive.—B. C. R.

OUTDOOR PLANTS.

ROMNEYA COULTERI.

This is popularly known as the White Bush Poppy, and is a very beautiful plant, although scarcely so hardy as one could wish. The flowers are white, very delicate in appearance, and sweetly scented, whilst they are borne on the points of

the new shoots. There is no doubt as to the beauty and value of this fine plant, but its tender character should make one cautious where it is planted. In the mild, balmy climate of Southern England it will succeed in the open if the soil is light and warm, but in more northern districts the shelter of a wall must be provided. As yet it is uncommon, as it has not been introduced many years from California, and is one of those things that must be regarded as fit only for really good gardens. In town gardens or small country plots it should not be planted.

4411.—*Stoncrop for a rockery*.—You may plant a variety of *Stoncrops* in the positions indicated. There are many kinds, many of them quite common; but, in spite of this, they are seldom grown so freely in gardens as they deserve. The little rockeries (so-called) that too often disfigure small gardens may be made, in a sense, pretty by planting plenty of the common *Stoncrop* in the "pockets," so that the growth may spread over the facing of the stones and make a soft, verdant carpet. *Stoncrops*, however, vary greatly in height, some being quite dwarf, others tall, and a notable instance of the latter section is *S. spectabilis*. The best known of the *Stoncrops* is *S. acre*, the *Wall Popper* as it is also sometimes called. It is too well-known to describe. There is a variety of it named *aureum*, which has the growth tipped with yellow, and this looks pretty in the spring. *S. Ewersii* makes a splendid edging, and it is a very easy plant to grow, the leaves being of glaucous tint, and the rosy-purple flowers are produced in such profusion that they form a perfect floral carpet. It is quite dwarf and hardy. *S. Sieboldii* is another very useful species, and the variegated variety of it is pleasing, but, unfortunately, tender; hence it is not wise to plant much of it in the garden, although it looks very well in pots. The foliage is of a glaucous tone, and the plant succeeds in ordinary soil.—C. T.

4425.—*Begonias in the flower garden*.—As a rule, the double-flowered kinds are not nearly so useful as hedging or border plants as the single-flowered sorts. They do not exhibit their blossoms so well; so many of them are drooping in habit that the blooms hang downward so much, and therefore cannot be seen to the same advantage as the more erect and single-flowered sorts. Apart from this, double-flowered kinds do not produce blossoms of the same quality over so long a period as the

singles do—the quality of the individual flowers commences to narrow down after the first rush of blooming; therefore, "*W. C.*" need not be so much surprised at the size of the blooms as compared to those first developed. The single-flowered sorts are far superior as bedding plants.—S. P.

4362.—*Herbaceous plants*.—A herbaceous plant is one that dies down to its base at some period during every twelve months. To reply to the remainder of your question would occupy a great deal of space, as the class is one of, if not the, most numerous we have, and even the most select list, with their seasons of flowering, &c., could scarcely come under the heading of short answers. Why not write to any of the firms advertising herbaceous plants in this journal? You would then get a full descriptive list, with prices, &c.—P. U.

4371.—*Christmas Roses*.—*Christmas Roses* may be grown in a London garden, either outside or in the conservatory; the latter would be preferable. Have strong plants in pots or tubs, and stand or plunge outside during summer. Put in good soil and give weak stimulants when the plants get straggling, if planted out work in last-mould or old manure well.—E. H.

4486.—*Nasturtium and Tropaeolum*.—The plants usually called *Nasturtium* are merely the annual forms of the genus *Tropaeolum*, many of which are perennials. Both are among the very best of town plants, and will grow and flower freely anywhere, as you have discovered. The climbing *Nasturtium* are the same as the "old tall kinds," but the dwarf annual varieties thrive almost equally well, and are far superior—at least, for bedding. There is also a race of perennial dwarf varieties, grown from cuttings, which are really grand for bedding or window-boxes, &c., in town gardens. *T. Fireball* (perennial, and grown from cuttings) is a fine climber, suitable for hanging baskets, &c., in summer, and blooms all the winter under glass. The *T. Lohmannii* varieties are also good. The tuberous kinds, such as *T. speciosum*, are too delicate for you. Try watering the *Scarlet Runners*, and syringing them overhead daily.—B. C. R.

4457.—*Gravel road and walks*.—The road and walks have been badly made, and not sufficiently drained. When the water passes freely away to the sides, and in addition the foundation is properly constructed with rubble, so as to lay the walk dry, green slime or Moss will not form unless there is a constant drip from overhanging trees. This slime may be kept down by a free use of weed-killers during summer, and unless the walks could be remade this would be the best course to adopt. Turning the walks over occasionally, hurrying the surface, would keep them in good condition.—E. H.

Salt thrown over the walk will kill the green fungus you speak of, so will the different weed-killers. Care must be taken in its application, or Box-edging, &c., will also be destroyed. Most of the weed-killers are strong and dangerous poisons, and must be handled and applied carefully.—P. U.

4460.—*Management of Hollyhocks*.—*Hollyhocks* may be raised both from seeds and cuttings. Seeds should be sown—if treated as hardy plants—in well pulverized soil in drills in May or early in June, or they may be sown in boxes under glass, pricked off in 3½-inch pots, and kept in pots till strong, wintering them in a cold pit and planting out early in April. They may easily be raised from cuttings and of July or beginning of August, using the side shoots for cutting, making each joint into a cutting, and thrusting them into a prepared bed of sandy soil in a frame kept close. I have struck thousands in this way, and there is only a small percentage of failures if the cuttings are taken at the right time, which is usually before the shoots get stiff and hard. The cuttings are potted off when rooted and kept in a cold frame or pit all winter; or they may be planted out on a warm border and be sheltered with braiches in winter. *Hollyhocks* make very large foliage and grow rapidly in early summer, and must have liberal treatment both in the preparation of the site and also when the flower spikes are forming. The want of this has led in dry seasons to the attack of the fungus which so disfigures the plants.—E. H.

These are easily grown plants, and make a gorgeous display in the flower garden. What the plants like best is a rich deep soil; they are gross feeders, and can take a large supply of farm-yard manure, trenched into the ground to the depth of at least 18 inches. The plants are

easily raised from seeds, or named varieties may be propagated as cuttings. I sowed seed in February of the present year, and the plants have all produced strong flower-spikes. They are now past their best. The seed was sown in a hothouse, and the plants grown on for a time there, until they were large enough to be placed in cold frames. There is no need to sow the seeds in a hothouse, but the object of doing so in this case was to obtain flowering plants the same season. Sow about the end of May, or in June out-of-doors, and the plants will flower well next season. It is not safe to leave the named varieties out in the open garden all the winter, as the change from wet to frost makes sad havoc of the plants. Cuttings taken in the summer may be wintered in frames, and the old plants when lifted in the autumn may either be planted out in frames or be potted up, and the growths which spring up from the base of the plants should be taken as cuttings in the spring.—J. D. E.

The principal requisites in the successful culture of this stately old favourite are few and simple—viz., deeply trenched soil, plenty of manure, and a liberal supply of water and liquid nourishment in dry weather, or, in a word, what is commonly termed "high culture." Seedlings make the best plants, though cuttings formed of small side-shoots, or those from the base of the plants, strike readily in sandy soil in a close frame during the latter part of the summer, and under cool and airy treatment make good plants. The seed should be sown in July or August, or as soon as ripe, in rich, sandy soil, and when large enough be potted singly, wintered in a cold frame or pit, and planted out in the spring—March or April. In light, warm, and well-drained soils the plants will frequently survive the winter in the open ground, and under the same conditions strong and forward young plants from either seed or cuttings may be planted where they are to flower in September or October; but on a heavy, damp, or cold formation the plants are never safe outside, and should be lifted and potted, or placed under shelter of some kind in the autumn. In dry, hot weather give a thorough soaking of weak liquid-manure once a week, and, if possible, mulch the plants with 4 inches of good, short, stable-manure or spent hops.—B. C. R.

These five plants need good culture. It is impossible to hope for fine spikes on poor ground, and the brilliant effects one sees in gardens at this season of the year are the result of a proper course of treatment. The soil must be deep and rich, and during dry weather in the summer months, such as we have experienced this year, it is important to give copious supplies of water. You may if you like give liquid-manure, but this is not really necessary, and the less one spills this kind of stuff about in the garden the better. One often smells more manure in gardens than flowers, and such things should be avoided. Prepare the soil well in the first place, get it thoroughly manured, and with help from the water-pot in dry times the Hollyhocks flourish, provided, of course, they are not molested by disease. The ground during the winter should not be damp, otherwise the crowns will have a hard fight. I remember well a noble row of Hollyhocks not far from the metropolis which was a source of pleasure for several years. The plants were in front of a row of Apple trees, and the splendid spikes of coloured flowers were thrown in bold relief. If you really wish the flowers to give pleasure in the garden—and I presume you do—there is no need to indulge in the fads of exhibitors, such as topping the spikes, thinning the blooms, and other points. Let the plants develop their own characteristic beauty. If you require information on propagating Hollyhocks, it has recently been referred to in GARDENING.—C. T.

4467.—Fuchsias.—I do not know the "Durobin Bedder," but a few of the best Fuchsias for a smoky garden are Daniel Lambert, Rose of Castile, Mrs. Marshall, and Sedan. Such kinds as F. gracilis, F. globosa, F. Riccartonii, &c., beautiful as they are in a pure atmosphere, are useless in a smoky one, as the flowers all drop before expanding.—B. C. R.

Easy propagation of herbaceous perennials.—Autumn is by far the best time for the above operation, and both Phloxes, Delphiniums, and many others of somewhat similar character can be readily increased as follows: The two species I have named are almost, if not quite, out of bloom, and if they are cut down at once a few healthy young growths will push

from the bottom. These are to be taken off close to the crown as soon as they reach a length of 3 inches to 4 inches. Put them singly into 72's, using a compost of leaf-soil, loam, and sand in about equal proportions, and, stood in a frame for a few weeks, they will root freely. In the spring the same plan may be followed, but it would need a heated frame, and they would not flower nearly so well the same summer as those propagated now. Plant them out in the spring into their permanent quarters; the second year they will be in full beauty. It is only by cuttings and divisions of the stools that we can secure named kinds of many of the finest herbaceous perennials. Division is also best carried out early in the autumn, as the portions have a chance of making a few new roots while the ground is still warm, and are thus better able to go through the winter, besides being ready to start in the spring. Spring division checks them very much.—P. U.

HYBRID DAFFODILS.

DURING recent years much attention has been paid to the hybridisation of the Daffodils—that is, crossing certain types with others to get new and distinct kinds. Our illustration shows a Hybrid Daffodil which will in time, doubtless, become popular, but as the bulbs do not increase at a great rate this is purely a matter of patience. Some very fine hybrids have been raised, especially by the Rev. G. H. Engleheart, who, as an amateur, deserves high praise for his persistent endeavours to increase the list of Narcissi, not with poor things, but really beautiful flowers. It is interesting to know that many wilding forms, natural crosses, effected in a state of nature, he has produced under artificial conditions, so to speak, and if few of the many kinds he has raised are worthy perpetuation, still those few will probably take a high place. Such a kind is Golden Bell, which has a large trumpet-shaped flower of varying shades of yellow, and a more robust and striking kind we have never seen. It is even finer than Horsfield. Raising new Daffodils is not such a serious undertaking as might be supposed. The great thing is to sow seed from crosses each year, and then one gets flowering bulbs every spring, otherwise inexhaustible patience is

A new Hybrid Daffodil.

necessary. It takes from four to six years for a seedling bulb to bloom and show its characteristic features. Sow the seed in shallow pans, and when the bulbs are about one year old they may be planted out. One of the finest Hybrid Daffodils raised by Mr. Engleheart is Golden Bell, already mentioned, and Chrysoator is another beautiful kind, the flowers large, and soft primrose-yellow in colour, very pleasing and refined in aspect.

CHRYSANTHEMUMS.

DWARF PLANTS.

PLANTS having but a single stem, and that from 6 inches to 1 foot high, carrying one large bloom, and that 5 inches in diameter, are extremely useful, so well as being somewhat novel. Plants of this kind can be had in pots not more than 3½ inches in diameter. Where an extra inch is allowed the blooms are all the better, no doubt, but the plants may not be so useful, as in the smaller pots they can be used so much better for filling vases in the dwelling-house, apart from their use on the front of the stage in the greenhouse. Such plants as these are not nearly often enough seen, certainly not so often as their merits deserve. They are well worthy of what little attention they require in producing them. The last week in August is a good time to take the cuttings. If they are inserted sooner the plants are apt to get too tall, and if taken much later the flowers are necessarily smaller, owing to the bud which gives the single bloom being a terminal one. Where Chrysanthemums are grown for the production of large exhibition blooms some of the points are almost sure to be broken off by various causes about the time stated, as, for instance, heavy rains, high winds, and birds alighting on them, the shoots at this stage being very brittle. Such shoots should be formed into cuttings 4 inches long, and some may be 6 inches long. Those with the bud just formed are the most suitable, as the height the plant will be when in flower can be more accurately ganged than when the cuttings are inserted before the bud is formed; the shoots grow several inches more after being taken off prior to the formation of the bud. Dibble the cuttings firmly into sandy, dry soil, using pots 2½ inches in diameter. Do not remove any of the leaves, except that from the base, where out square across, the plants are all the better for having their foliage intact. Well water to settle the soil securely about the cuttings; plunge them in a gentle hot-bed, if available, as here they strike root so much quicker than in a cold frame. If, however, the bottom-heat cannot be had, plunge the pots in coal-ashes in a cold frame, keeping the frame close until roots are formed, with the exception of admitting air for an hour or so to dissipate condensed moisture off the leaves. Whether the cuttings are placed in a cold frame or a hot-bed they should be shaded from hot sun, as this will make the leaves flag and most likely make some of them drop off, which is detrimental to the appearance of the plants. Syringe the foliage every afternoon of fine days, and by keeping the frame nearly close roots will be formed in about a month, when more air should be afforded, increasing the supply until the plants will bear full exposure without flagging. The best position for them at this stage is on a shelf close to the glass in the greenhouse. If it is desirable to have large blooms, shift the plants into pots a size larger, using a rich compost. Of course, tops can be taken from the ordinary plants for this purpose, but of course it is at the sacrifice of large blooms on the plants grown for the express purpose. Varieties belonging to the Japanese section are the most suitable as the peduncles are so much stronger than upon the incurved sorts; plants of the latter section need support, while the Japanese section are mainly self-supporting. E. M.

4430.—**Passion-flower in fruit.**—Strong plants are fruiting freely this year, but there are only two varieties which are fit for eating. One is the Graudilla, which requires a stove temperature, and the other is the edible Passion-flower (*Passiflora edulis*); the last named may be grown in a warm greenhouse. I have sometimes tasted the fruit produced by other varieties, but have always found them bitter and disagreeable. The fruit of the edible Passion-flower makes an excellent preserve. (They are gathered before quite ripe, and preserved whole in sugar.—E. H.

ORCHIDS.

EPIDENDRUM FALCATUM.

FROM "W. W." comes a flower of this old species for a name. He says he cannot send a leaf because it is too large and weighty, but he sends a sketch, which he hopes will do as well. Equally so in this case, my friend, and I give above its most correct name, which was given it many years ago by Dr. Lindley. Curiously enough, although the plant is so distinct in appearance, it has had many names given to it, some of which I give here, in case "W. W." should be told another name for it, and he might think I had misnamed his specimen. It was called *E. odorifolium* by Bateman, and figured in his work on the "Orchids of Mexico and Guatemala," and also *E. Parkinsonianum* by Hooker, who figured it in the "Botanical Magazine" under that name. *E. laetiflorum* it is to be found under in some gardens, and others of less import. The plant is widely scattered throughout Mexico, in various situations and under various conditions, and varying somewhat in colour from pale-yellow to white and pale greenish-yellow, usually growing upon the stems of trees, though not infrequently it is found upon rocks. It is by no means a new plant, having been found, in the first place, upwards of sixty years ago; but it is not much seen in cultivation, though not being considered showy enough by the majority of Orchid-growers, and I do not suppose my friend "W. W." would have had it but for its accidentally popping up in a mixed lot of Mexican Orchids, which he purchased at a prominent sale. However, the flower sent me represents a very good variety of the plant, and I advise my friend to preserve it. I have found the plant to grow well with me in the Odontoglossum-house, at the warmest end. It thrives best on a bare block of wood, saving a little Sphagnum Moss, just to keep a little moisture to the plant; but in the winter season it will withstand a great amount of drought, but it is best not to permit it to become so dry as to allow the leaves to shrivel. The plant has a stout rhizome, which at intervals produce short stems, which bear a single lanceolate, thick, fleshy leaf, which is from 9 inches to a foot long, deep-green. The peduncles spring from the base of the leaf several together, each one bearing but a single bloom. The sepals and petals are similar (yellowish-green), the lip being of a more decided yellow colour.

MATT. BRAMBLE.

CATTLEYA BOWRINGIANA.

It is less than a single decade ago since the Messrs. Veitch, of Chelsea, introduced this plant into our gardens from Central America, for which we have much to be thankful for, and yet there has been much disappointment upon first flowering the species, as its beauties cannot be seen when it is poorly grown and flowered. But in the case of "G. T. H." who sends me a series of flowers, nine varieties in all, there can be no doubt of its great beauty, especially when he tells me he has none "with less than eight blooms on a stem." I do not think there was the slightest utility in "G. T. H." numbering these flowers separately, for the most of them differ from each other very slightly, and that chiefly in the shades of the sepals and petals, and slightly in the maroon band in the lip, so that there can be no use naming these varieties; but he may take it for certain that 3 and 7 are the poorest of the lot. I do not write this in any derogatory manner respecting this plant; indeed, I am much obliged to my friend for sending me such a fine sample, and all the kind things which he says respecting the teacher will be carefully noted. This plant with "G. T. H." appears to be like many others of the same family throughout the country, a month or two earlier than usual; but if it will become an established thing to become an earlier bloomer I cannot say; but one thing which may have had something to do with this is the starting into growth in this spring, it being very warm and sunny, would have accelerated them; therefore, I would advise "G. T. H." to keep his plants a little drier in the rest season, and so retard them from starting into growth quite so soon; but this must not be done by ever-drying but by reducing the temperature by a few more degrees for the rest season. We sell the plants grow naturally in an atmosphere

highly charged with moisture, even in the dry season, whilst in the growing season the rainfall is excessive, so that my readers may take notice and always maintain a large amount of atmospheric moisture about this plant. Now this same remark I have had to make in a personal manner to several friends to whom I have paid a visit this season, and whose plants of this and several other species I have noticed to be getting infested with thrips and red-spider, a sure sign that the atmosphere is too dry and too hot, and *C. Bowringiana* is very liable to the attacks of both insects under these conditions; but if treated congenially it will be found to be both a free grower and a free bloomer. Moreover, it has usually flowered in the month of October. The flowers last well so that it may frequently be seen in bloom until the end of November. Like the majority of the Cattleyas it must be well drained and potted in good rough peat and chopped Sphagnum Moss, pressed down firmly, but it must not be overloaded with soil. Water carefully and somewhat sparingly, but always keep the air well charged with moisture.

MATT. BRAMBLE.

CYPRIPEDIUM PURPURATUM.

WHEN the Messrs. Loddiges published their Orchid catalogue nearly fifty years ago there were but five only of these coriaceous-leaved Lady's Slipper-plants in cultivation. What a difference exists at the present day, as may be seen by the holly but commodious catalogue of Slipper-plants published by Mr. R. H. Messtres, of the Woodlands, Streatham, and of others who are specialists with this genus. The plants stood in the following order: *Cypridium venustum*, introduced in 1818; *C. insigne*, 1823; *C. purpuratum*, in 1836; *C. barbatum*, 1840; and *C. barbatum onguistatum*, 1840. These were the only kinds which could be obtained in the year 1845. The flower of *C. purpuratum* sent to me by "John Vansittart," is, however, a very fine one, much better than a dried flower which I have of this species, which bloomed with me nearly forty years since, and when we were all in ignorance of its native home; but now it has been found to inhabit Hong Kong, where it has been ruthlessly extirpated, so that at the present time it has become quite scarce. But I have little doubt but that it occurs in the Chinese coast which lies opposite, and where I trust it will long be allowed to remain undisturbed, or at least that it will be gathered with care and discretion. I am under the impression that there yet remains a lucky find for someone in getting that great beauty *C. Fairieanum*, and I wonder that the cross-breeder has never resorted to the plan of obtaining it from seed in this country; but it will be a very lucky find for the first man that can put his hand upon it. My opinions upon this plant and its habitat I communicated to my old friend Boxall, the traveller for Messrs. Low, when I last saw him. If he is in the East now searching for it I cannot say, but he is a very likely man to find it. But to return to the species whose name stands at the head of this paper; it is a plant having nice tessellated foliage, much in the way of *C. barbatum*, and with a bright-coloured and very distinct flower; the dorsal sepal in that now before me being broad, almost round, having a slight white point, with numerous streaks of purple running through it, the lower sepal very smaller and more pointed, the petals standing at almost right angles. These are of a rich, purplish colour, tinged with green, veined with black, the lip is large for the flower, brownish-purple, veined with deeper purple, the infolded part being bright rich-purple. I would advise my friend to drain the pot or pan that it is put into in a thorough manner, using for soil a mixture of turfy light loam, good fibrous peat, and some chopped Sphagnum Moss, using a little sharp sand in potting; keep the plant moderately moist, and it will grow well in the temperature of the Odontoglossum-house at the warmest end, and during the winter season it should have a temperature of about 34 degs., and he kept fairly moist, with a moist atmosphere. Under these conditions it will thrive better and grow quicker than if kept hotter.

MATT. BRAMBLE.

381.—Growing *Ocologyne* (Illustration). This is one of the easiest Orchids to grow, and

will do admirably in any stove where the temperature is about 55 degs. in winter. Grow the plants in flower-pots, not on blocks. They should be planted in a compost of good fibrous peat, a little fibrous loam, and a third part of Sphagnum Moss. Mix potsherds and a little charcoal with the soil to keep it open. The compost should be raised above the rim of the pot in the form of a mound. The plants are making their growth now, and should not be disturbed until growth is completed. Give them a good supply of water until the bulbs are fully formed, when they do not require more than just to keep the bulbs from shrinking. The flowers will appear in the spring. After flowering repot them as advised above.—J. D. E.

FRAGRANCE IN CARNATIONS.

CARNATIONS are in danger of losing one of their greatest charms—namely, a delightful scent. It is important to urge that they should be scented, because by far the majority of present-day kinds—I allude chiefly to garden euffs, whether English or French—are as scentless as Baroness Rothschild Rose. It is true that these fine kinds appeal to us strongly through other channels, by reason of such merits as vigour, freedom of flowering, fine form, rich colour, &c., and they find much favour; but the crowning charm of all which we seek, too often in vain, is that of scent. All who look for the natural charms of Carnations must surely deplore the want of scent in the modern varieties, and the sooner we remedy the evil the better. Carnations doubtless have not become all but scentless at one step. In the improvement of recent years the charm of scent has been ignored or forgotten. This proves how observant and watchful we should be, lest whilst doing good in one direction by developing and bringing out the finer qualities of a flower we disregard natural charms. It is not predicting too much that in another decade scentless Carnations will be the rule, and a scented kind a very rare exception. This must happen if we rely upon those who keep on raising new kinds from a scentless source. A little wholesome agitation did much good in bringing to the front the merits of self Carnations, and now that we are satisfied upon the point and convinced by results of trials, let us agitate for scented Carnations. We shall not be successful perhaps in inducing the orthodox florist to make the slightest deviation from his narrow way, but the love of Carnations is making headway. Many of its lovers have no aspirations beyond fully enjoying and appreciating the flower, and to these we must look.

B. W.

4373—*Lily of the Valley*.—Directly the leaves die down dig up the roots and free them from weeds, making a new plantation on a new site. It matters little what aspect is chosen, *Lily of the Valley* will succeed if properly managed. The same quantity of flowers cannot be expected from a newly-planted bed as one established for a year, but a crop will be obtainable even then, though possibly not quite so fine. When replanting it will be a good time to thin out the roots and increase the space of the beds, as there will be plenty of thinnings, picking out the smaller roots to be planted by themselves. Trench the soil 2 feet deep at once, planing in the top trench a good coating of manure, so that the roots will readily find it. Keep the surface-soil on the top, returning that from the bottom of the trench back again to the same place. In planting pull the roots to pieces; not more than a couple of crowns should be put in together for fear of overcrowding them again. The crowns need not be buried more than an inch under the surface. Cover the whole bed with half-decayed manure and leaves, 2 inches thick, allowing it to decay. Not only will this mulching preserve the roots from frost, but will prevent the evaporation of moisture during the summer. After the flowering season is past supply the roots liberally with liquid-manure to assist in the swelling of the crowns, and thus lay a basis for future flowering.—S. F.

4483—*Gas-lime and wireworms*.—A bushel per rod may be used on the land in autumn if the land is not ready to be cropped before spring, and the heavier the dressing which can be given without injury to the next crop the better the chance of getting rid of the wireworm, as they are not very difficult to clear out of newly broken-up land especially.—E. B.

TREES & SHRUBS.

CHERRIES AS ORNAMENTAL FLOWERING TREES.

THE planting season is fast approaching, and therefore I think it is appropriate to draw attention to the great beauty of the Cherries whilst in flower. At the time for planting them, and where a note has been made of their usefulness it will be advisable to secure the trees and plant them at once. In my own case I have observed that after the double varieties attain a fairly good age there is a tendency towards a canker, as in the fruiting Cherries. Rather than allow a tree to remain when it has in a manner become unsightly, it is much better to cut it down and plant fresh, but not altogether in the same place without an entire change of soil. When a tree is seen to be on the wane it is just as well to plant afresh; then by the time the young tree is established the old one can be removed without being greatly missed. The illustration depicts a young tree grown as a standard, which is by far the better plan. It will be noted on reference to the engraving that there is an undergrowth of foliage; this is as it should be, and exemplifies the advantage of the standards over dwarfier bushes. It is not, of course, necessary to keep to the double varieties, although whilst in flower they last longer in good condition. The single and fruiting kinds can also be planted for purposes of ornamentation as well, although methinks they are not so very often to be met with. For example, why should not the Morello Cherry be so cultivated? I have seen it thus grown in a most successful manner, forming beautiful heads. First there is the handsome display of bloom, then there is the fruiting season. We do sometimes see the Weeping Ash on lawns, why not the Morello Cherry as well, and grown in the same way? In all probability the fruits would escape the birds more than when planted in the kitchen garden in those gardens of medium size, because the tree would stand by itself. The reason why standard fruit-trees of all kinds are not more extensively planted in our shrubberies is not that they are not beautiful, surely? I think it is rather that because it has been so, so it must still be. A well-clothed, but not necessarily a pruned, tree of the Morello Cherry would upon a lawn be a beautiful object. It is easy enough to grow it thus. The soil need not be in any case of a rich character; I would rather have it otherwise. The following are useful double varieties to plant in shrubberies—viz, *Cerasus Avium* multiplex (the double form of the wild Cherry), *C. domestica flore-plena* is a strong-growing variety, but probably not so much so as the foregoing, *C. serrulata* (the double white Chinese Cherry) is, I think, one of the most useful of all; it flowers freely, and is not so strong a grower. Of the single note should be made of *C. Juliana* (St. Julian's Cherry) and its rose-coloured variety; also of *C. Padua* (the Bird Cherry) and its pendulous variety. Besides these there are the single varieties of the doubles first quoted, and last, but not least, the Morello aforementioned, which should be chosen with clean, well-grown stems. H.

4155.—**Climbers**—Yours is a very vague question. You do not even say whether you want your climber for the outdoor or indoor garden? For the open few things would give you more variety than Clematises, and by choosing those which flower at different seasons you would get greater satisfaction; thus, for spring bloomers you might have Lady Londborough (silver-grey), Lord Londborough (deep-maroon with magenta bar), and Stella (light-violet with reddish bar). For summer

and autumn: *C. Jackmani* (intense violet), *Jackmani alba* (white), *magifica* (reddish-purple), and *Mrs. James Bateman* (pale lavender). For indoors few things are prettier than the two common varieties of *Plumbeago capensis*, the French blue and the white; add to these some of the numerous varieties of *Fuchsia*, and you need wish for nothing better.—A. G. BUTLER.

—The following will be found a good assortment of hardy climbers, from which may be selected plants suitable for all aspects, as well as for covering arches, porches, training espaliers, &c.: *Ampelopsis hederacea*, *A. Veitchi* (one of the best creepers for covering north walls), *Cotoneaster Simonai* (this also does well in north aspects), *Cydonia japonica*, *Escalonia macrotheca*, *Eucynome radicans variegata* (a very useful, neat climber, will cling like Ivy), *Honeyauklee*, *Red Dutch*, *Scarlet Trumpet*,

Clematises, a large number of kinds, in which the flowers represent a great diversity of colouring, varying also in shape. I do not care for the very big-flowered kinds, which are ungainly and, unfortunately, somewhat tender in constitution. *C. montana*, which has white flowers, is very beautiful, is another fine kind, one of the best of all climbers, free in both growth and bloom. The number of Clematises is great, *C. viticella*, and many others, but the two kinds to grow first are *C. Jackmani* and *C. montana*. These you could have the handsome-leaved *Dutchman's Pipe*, a climber which gives a variety and is not too common in gardens. *Ivies* in variety, although these are not for beauty of flower; but there is great charm in their leaf-colours, from glossy green to fine alvery markings. *Jasmines*, which bloom when few other things are in flower, is a great gain. Its leafless shoots with rich-yellow flowers, which make a bright show in the winter and early spring months. It will live in almost any position, and I have seen it very beautiful in quite inhospitable gardens. The *Crimson Jasmine*, which has white flowers, is very sweetly scented, and to be valued for that reason. Then the *Honeyauklee* may be thought of, the *Passion-flower* in warm, fairly sheltered spots, and the hardy *Violes*, which are graceful, and the leaf-colouring is striking.—C. T.

4470.—**Araucarias**—I should say that your tree has been struck by lightning, which has caused it to go off so suddenly. There does not appear to be any other explanation. Such instances of injury are not uncommon. The harm done is generally seen within a few days after. You had better remove the tree, as it is past recovery.—J. C. C.

—The tree which has lost its lower branches has got into the cold clay upon mention. A cool, gravelly bottom suits this Pine, but it must not be clayey. I have had under my notice the finest avenue of this grand Chilean Pine in the country, the majority of them being from 50 feet to 60 feet high. They will grow anywhere up to the height you name, but as soon as the roots reach a wet and cold soil the lower branches suffer. Your other trees will be sure to go like it in a short time.—P. U.

4474.—**Propagating a Magnolia**.—Magnolias can be best propagated by layers. If you can bring one of the young branches down on the ground make up a bed of sandy soil to receive it, and when bent down get a strong wood peg and secure it firmly in the ground, burying the bent part of the branch 3 inches under the surface, placing a stick and tie to the point of the shoot to bring it slightly erect. It will take two years before the layer is ready for transplanting. I think your youngest tree requires some rotten manure stirred in about its roots.—J. C. C.

—By far the best way to propagate this shrub is to graft upon seedling stocks. They are also easily increased from layers, using a peaty compost. It is best to layer a shoot into a box of prepared soil, as they are very impatient of disturbance when rooting has commenced.—P. U.

—Layering is a more certain method than cuttings, and the layering may be done now.—E. H.

4476.—**Laurels and Rhododendrons**—If laurels and Rhododendrons require cutting hard back the work should be done in spring early in March. Simply cutting out young shoots for the sake of symmetry may be done any time. Taxodias should be pruned in autumn after flowering. This will let the much needed light into the dense winter foliage.—R. H.

—The spring is the best time to cut these plants, and it should be done as soon as they start into growth. The Taxodias also should be cut in the early spring. Outtings of any kind under hand-saws should not be exposed until they are formed.—J. D. E.

—This is not a good time to cut Laurels or Rhododendrons, especially the latter, or the bloom buds for next year's crop would be sacrificed. There would be no harm in removing a shoot or two from the Laurels for the sake of appearance, but a general close pruning is

OUR READERS' ILLUSTRATIONS: Cherry-tree in bloom. Engraved for GARDENING ILLUSTRATED from a photograph sent by Mr. S. V. Harcourt, Malwood.

Aureo-ronclata, *Ceanothus dentata*, *C. Veitchi* (should be planted against a south wall), *Corymb elliptica*, *Wistaria sinensis*, *W. s. alba*, *Ivies* in variety, *Clematis* in variety, including *Jackmani*, *Snow-white Jackmani*, *montana* (winter-flowering), and *Flammula* (autumn-flowering), *Jasminum officinale major*, *J. nudiflorum* (winter-flowering), *Lycium barbatum* (Duke of Argyll's Tree), *Pasiflora cerulea*, *P. Constantia* (should have a good aspect), *Passiflora* (*Fire Thorn*), *Roses* in variety, to include *Gloire de Dijon*, *William Allen Richardson*, *Cheshunt Hybrid*, *Maréchal Niel*, &c. The situation should be well exposed, and the soil changed if necessary.—E. H.

—There are a great number of climbing plants, some very beautiful and showy, others of little interest. Possibly one of the best of all climbing plants is *Clematis Jackmani*, which has rich purple-violet flowers. Indeed, it is a familiar object in many gardens, both large and small. But there are many other kinds of

altogether wrong at this time of the year. I advise that pruning be done early in the month of February, for the reason that the plants are not so long bare in the stems if cut severely as they would be if cutting was done in the autumn, or even at Christmas time. Many persons do all their shrub pruning at that time, so that the clippings may be utilised for decorations at that season. Rhododendrons are best pruned directly the flowering season is past; the plants are then just commencing to make their season's growth.—S. P.

4158.—Striking *Ceanothus*.—Cuttings of the young shoots, when getting a little firm, will root in sandy soil under a band light. The same shoots, when ripe, will also root, but not so quickly. If there are shoots near the ground they might be layered now.—E. H.

— You may propagate these at any time now. Choose wood that is ripe, but has still got a few leaves upon it. A cold frame and sandy soil is all that is necessary. Do not make the cuttings too long. If you can layer a few shoots from the bottom you will obtain a strong plant much sooner than from cuttings.—P. U.

TRANSPLANTING EVERGREENS.

THERE appears to be much difference of opinion as to the proper time for transplanting Evergreens, but there can, I think, be no question as to early autumn and spring being the best seasons, and the month of September and that of April should be seized on, and the work pushed on then with as much expedition as possible. In the removal of Evergreens the great thing is to be particular and careful in the lifting; but, unfortunately, few workmen seem alive to the importance of this, as they dig up close, as if roots were of no consequence whatever, and cut or maim all they come near; but instead of that happening, every one should be preserved free from injury, and then the plant they are attached to stands a good chance of soon starting again and re-establishing itself. This being so, it will be seen how necessary it is to open out a trench all round well away from the stem, the distance, of course, being ruled by the size and age of the shrub to be operated on, and then by the aid of a steel fork work away the soil and keep clearing it out till the ball is so reduced as to be small enough to move with the strength or appliance at hand or disposal. The first preliminary, however, where there is much transplanting to be done, and it is better to proceed where there is only a little, is to

DIG THE HOLES where the plants are to go, and in doing this plenty of room should be given, as the bigger the hole the easier will it be to plant and spread out the roots properly and for them to ramify after and get fresh hold of the soil. In placing the plants in position the chief point is to see that they are not too high above the ground or too deep, and to keep them at the original level, as to bury the stem up is bad, and equally as to have the collar too elevated, unless on heavy or wet land where the soil can be raised and made up to it, as then the ball would be too much exposed to the weather. Not only do Evergreens need lifting with great care, but the filling in is almost as important, and this should be done piecemeal as it were—that is, a certain portion of fine soil thrown over the roots and then water cast on with force, so as to carry the soil along with it and stop every cavity or interstice there may be around or under, and to aid in this the top of the shrub should be swayed to and fro, after which the holes may be finally filled. The next thing to be done is to mulch with any loose litter, long strawy manure, or any material of that kind that will shade and prevent evaporation, as uniformity of moisture must be maintained to get freshly moved Evergreens to do really well. Steadying the heads should also be attended to, and this may easily be done by a stout stake driven down near the main stem of each plant and tying to it, and if the shrubs are afterwards syringed each evening overhead, or sprinkled with water by other means, so as to prevent flagging, they will scarcely feel the shift, and be quite prepared to pass safely through a hard winter or face the bright days of summer. W.

Drawings for "Gardening."—Readers will kindly remember that we are glad to get specimens of beautiful or rare flowers and good fruits and vegetables for drawing. The drawings so made will be engraving in the best manner, and will appear in due column in GARDENING ILLUSTRATED.

FERNS.

CHOICE FERNS.

MOHRIA THURIFRAGA.

In reply to "Brixtonian," "V. R.," and others, I may say that, notwithstanding that nearly half a century has elapsed since this plant was introduced to this country, it still remains one of the rarest, as well as one of the most beautiful, of evergreen cool-house Ferns. It has, to an ordinary observer, the appearance of a Cheilanthes, whilst others have likened it to the North American deciduous *Woodсия obtusa*. The plant

Frond of Mohria thurifraga.

appears to have been first introduced to the Botanic Garden of Berlin, a garden singularly rich in the species and varieties of plants; from there it was sent to our own Botanic Gardens at Kew, and a few years ago could have been found in many collections throughout the country, but it is now to be reckoned with the rarest of our cultivated Ferns. Our illustration affords a good idea of the beauty of a small frond of this plant, which is the only species known. When the plants are well grown the fronds attain a length of 2 feet, although they more frequently grow only about 12 inches, and when fertile the sori are very conspicuous, being thickly clustered upon the points of all the lobes. The fronds, which when bruised are very fragrant, hence its name, are erect, twice divided, and very equal in width throughout, the sterile ones being wider than the fertile; the pinnae are deeply lobed, bright-green, and smooth on the upper side, but beneath they are furnished with woolly ferruginous hairs; the stem also is densely clothed with longer hairs of the same colour. In the kind called *schiffelii* the fronds are more prostrate, and the lacinations of the pinnae are more delicate. That it is a variety only of the species has been proved by the fact that both forms have been obtained from spores saved from one plant. The plant is a native of the Cape and Natal, and various of the African Islands, in which, probably there still lurk some more undiscovered species. It should not be overpotted, and for soil use a mixture of peat and light loam and about an equal part of nodules of sandstone. It enjoys a fair amount of water to the roots, but should not be watered overhead, and it thrives best in the temperature of a warm, dry greenhouse. This plant grew well and attained its maximum size under the above conditions in the Messrs. Rollison's establishment

at Tooting, the above illustration having been taken from one of the young plants grown there. J. J.

4464.—Fern seeds.—The dry air of a room is not the best in which to raise Ferns from seed, but a great deal may be overcome by patience and careful management. The successful way in which many ladies manage Ferns in rooms often surprises me, and it shows that even the raising of them from seed is not an impossibility. I hope you have only the seed of fairly hardy sorts, as you are not likely to succeed with tender ones. The great point in the management at present is to keep the pan away from a strong light, and not to disturb the young seedlings by washing out of their bed. The soil in the pan must be kept moist, this is best done by holding it three parts its depth in a pail of water for a minute or two, and then lower it sufficiently that the water flows gently over the surface. Four months should be allowed for the seedlings to appear.—J. C. C.

— In a month or six weeks from sowing the "hair" ought to begin to appear, but the time varies considerably, according to the temperature, season, freshness or otherwise of the spores, and other conditions. If the "seed" you mention was sown and good, and was sown upon a roughish surface of loam or leaf-mould in a well-drained box or pan, it ought to germinate—that is, if the soil is kept in an even but moderate state of moisture, and carefully shaded from sun. You must prick the seedlings off—at first in little clumps—as soon as the first tiny fronds can be seen, and still keep them moist and covered with glass.—B. C. R.

4480.—Plants for winter.—There are a good number of people who would like to know what plants to put in after the summer flowers that will flower through the winter, because they have found that those they have tried very often fail owing to the severity of the weather, and if these who wish to try start with the understanding that everything depends on the weather they are not so likely to be disappointed in the end. If people who are so fond of flowers would make all their small flower-beds into one large one, and fill it with hardy flowers chiefly, they would then have some space to devote to subjects that bloom in the winter and early spring as well as summer. In mild weather the Christmas Rose flower from December to February; then follows the Winter Aconite, Snowdrops, Hepaticas, and Primroses. Next to these comes the Siberian Squills (*Scilla*), Glory of the Snow (*Chionodoxa Lucillia*), Tritelia uniflora, and Single Yellow and Dark Wallflowers. *Erica carnea* blossoms very early in the spring, as also does those low-growing, sweet-smelling deciduous shrubs *Daphne Mezereum*, and *D. alba*. Amongst herbaceous and rock plants that bloom very early in the spring I may mention the Leopard's Bane (*Doronicum*), *D. austriacum*, and *D. plantagineum excolsum*. You, of course, know that the ordinary Crocuses will make a garden very gay in the month of March. Then there are the early Single Tulips that follow directly after, and to succeed these there are the Hyacinths and late-blooming Double and Single Tulips. So you will see there is a possibility of your having a bright garden early in the year and onward.—J. C. C.

4472.—Scale insects.—Do not use paraffin-oil; it is dangerous, especially to Peach trees. Make a strong solution of Gishurst Compound, 4 oz. to the gallon, and go over the trees twice, as soon as the leaves, or, at least, before the buds get permanent, and see that every part of the trunk and branches are well dressed with the solution. Give another look round before the blossom-buds open in spring, and touch up with a small brush all the suspicious spots. If properly done this will be effectual without injuring the trees.—E. H.

4478.—*Agapanthus umbellatus albus*.—I am pleased you have been successful with this beautiful plant, which should be grown more, whereas one gets always the blue species, and it naturally becomes rather tiresome. I never heard of the White *Agapanthus* being forced, and there are many better and more profitable things I should think for the purpose. Be content and enjoy its fine flowers produced naturally.—C. T.

HOUSE & WINDOW GARDENING.

AUTUMN WINDOW-BOXES.

As the summer (which has truly been a glorious one) wanes the flowers in our window-boxes, sorely tried by the great heat, look more dilapidated than usual, and must be removed at once. But there is yet time to display a few more fresh blossoms, and these will do best in pots sunk over the rim in Cocoa-nut-fibre, or, better still, Moss, carefully looked over before using it for insects, &c. Plants potted up from the garden may be utilised for the windows in autumn. Nice little specimens of early-flowering *Chrysanthemums*, pots of *Asters* which are late in blooming, *Carnations* too (which, if put out late, often bring blossoms in September) can be lifted carefully from the ground and potted for the window. In this way *Carnations* and other summer flowers, such as *Margerites*, can be lifted and displayed in a window-box until the frosts begin, when it is easy to take them into the room, where they will continue to produce their blossoms for some weeks. Directly the frost arrives in earnest, the boxes should be cleared of flowering plants and arranged for the winter and early spring. Perhaps the prettiest winter window-boxes are those which contain neat little plants (in pots) of the *Berried Aucuba*, alternating with specimens of the beautiful *Berberis* (*Berberis aquifolium*), which is covered in winter with rich-purple berries and bright-reddish foliage, bringing, too, its pretty sprays of yellow blossoms in the early spring. Various small *Firs* and *Yew-trees* are sold, too, for this purpose, but some of them have a funeral look which is not attractive, others are so stiff in form that they are far from elegant, unless grown with hanging greenery, such as *Ivy* or the beautiful hardy *Fern*, *Scolopendrum vulgare* (*Hart's-tongue*). This makes a lovely trailer for a winter window-box, and can so easily be grown in pots in the area during the summer, when the damp, cool air will suit it well. Pots of *Ivy* or *Hart's-tongue*, sunk in Moss, alternating with pots of bright *Red Tulips* or *Hyacinths* in early spring are very charming, and the bulbs can be easily brought on in a window if potted in good time. Those who do not care to have a succession of pot-plants for their window-boxes can plant them in October with hardy bulbs, such as *Tulips*, *Hyacinths*, *Snowdrops*, *Crocus*, or *Daffodils*, mulching these with Cocoa-nut-fibre or Moss, when they will have a bright display in spring. Another plan is to plant the boxes in autumn with seedlings of *Forget-me-not* (*Myosotis dissitiflora*) and deep *Brown Wallflower*, alternated, if the boxes are large, with neat little plants of *Enonymus variegata*. The effect of the bronze and turquoise mass of bloom in early spring is very good, and the scent of the *Wallflower*, when the windows are opened, is delicious. Good stout little plants which have been raised from seed early in the summer should be collected, and they will be better for a mulch of fibre or Moss, as recommended for the bulbs. I. L. R.

4418.—**Mountain Ash berries.**—These are perhaps the most difficult of all berries to preserve for winter decoration, as they have an inveterate habit of dropping off their stems, which is very disappointing. The best way to keep them is to pick the bunches just before they are ripe, dip them into clear, rather thick gum-water, dry them thoroughly, and then pack them away in a tin box with an air-tight cover, using layers of cotton-wool to place between them. Many berries (such as those of the dusky *Iris*, which, in the South of England, are very plentiful in the hedges) may be preserved in this way. Some people cover the ends of the stems with sealing-wax also, but the great thing is to exclude the outer air thoroughly, and also to pick the berries at the right time—i.e. when they are fully expanded, but not ready to drop. Berries of all sorts are very fine this year, the lovely three-cornered carmine spindles berries, those of the *Eglantine* or *Wild Rose*, the dusky *Iris*, and even those of the *Hawthorn* being useful for church decoration at Christmas when preserved in this way. Beautiful was the too of the brilliant berries of the *Black Bryony* can be obtained in autumn, in the hedges. *Wild Bryony* being less common, but also supplying bright-red berries for this purpose. "M. O. T."

might also try various other berries, such as may be found on the shrubs in most well-stocked gardens—*Cotoneaster*, *Aucuba*, and *Berberis*, for instance, which are highly decorative, and of which many varieties are now cultivated. But the intense carmine of the *Mountain Ash* is certainly our finest colour in berries, and it is well worth a little trouble to keep them for winter decoration. They are said to keep for some time in a strong solution of salt and water, covered with this entirely, and only needing rinsing in fresh water before using. The writer not having personal experience of this plan, can only suggest it as worth trying.—J. L. R.

"M. O. T." may preserve the berries by placing bunches in a deep earthenware pot, pouring over them strong brine and water, with a thick layer of mutton fat on the top to exclude air. They will only require rinsing in fresh water and slowly drying to be fit for use.—EAST ANGLIA.

WINTER-FLOWERING BEGONIAS FOR A ROOM.

These beautiful plants which have been extraordinarily improved of late years by hybridisation with the tuberous summer-flowering varieties, now bring plenty of splendid blooms during the winter months, and are the most useful for room decoration when other flowers are scarce. Their flowers, too, are lovely for cutting, and last a long time in water, so that we can scarcely have too many of them in winter, and every lover of flowers should add a few good specimens of winter-flowering *Begonias* to his collection. One of the handsomest varieties is *Winter Gem*, with brilliant red flowers about 2 inches in diameter, which last as long as six weeks without dropping. *John Heal*, too, is very good, bearing eight or nine brilliant pink blossoms in elegant racemes, well shown above the handsome foliage. *Adonia*, too, is somewhat similar, with blooms of a carmine tint. *Begonia Carrieri*, a most floriferous variety with pure-white flowers, is charming for cutting, and also

too much pot-bound to flower almost all the year round, good drainage and an abundant supply of water when in full growth being essential to their well doing. Young plants raised from cuttings in the spring can now be procured and potted on, pinching back the mere vigorous shoots where they grow out of shape. If wanted for immediate effect, large plants should be bought, as the first year they are too small (when raised from cuttings) to be very effective. A temperature of about 60 degs. is necessary for them when in blossom. R.

PINK HYDRANGEA CULTURE FOR MARKET.

In reply to "B. S.," "H. T.," and others, the method of culture generally adopted is as follows: A few large old plants will be found to furnish a tall times in the growing season an abundant supply of cuttings. These are removed with a sharp knife during the months of May and June, and are inserted four or five in a 5-inch pot in some sandy soil. If kept well shaded and moist they soon strike root, when they are immediately potted off singly in good, heavy, rich loam, mixed with a little decayed manure. They are placed in a pit where they can have an abundance of air, and when established the sashes are entirely removed. The young growths are not stopped, the object in view being to produce sturdy plants, with well-ripened terminals. Ende About the end of the month of July they will be ready to be placed in their flowering pots, 5-inch or 6-inch ones being quite large enough. In potting, the soil in the pots is made very firm indeed, and then they are arranged in convenient sized beds out-of-doors, exposed to all the sun and air possible, and also with liquid-manure; good guano makes as good a one as any that can be used. The plants will not grow more than a few inches in height, for as soon as the pots become filled with roots growth ceases in that direction, and the

A well-flowered Pink Hydrangea in a vase.

makes a beautiful table-plant, the blossoms being borne in sprays all over the plant which is of a regular, bushy shape when well grown. PRINCESS BEATRICE is a very good *Whitn Begonia* too, and *Waltonensis* brings a quantity of bright-pink blossoms, while *Knowsleyana* is an excellent winter-flowering variety, bearing a quantity of flowers of the palest pink. *Topaz Begonias* are not difficult to cultivate. They only need potting on before they become

energies of the plants afterwards seem devoted to the perfecting of the embryo flower-buds. By the end of the month of September the foliage will show signs of approaching ripeness, and when that happens a slight diminution in the supply of water will be advisable; but this must not be carried too far, as, by so doing, the plants would be weakened. As winter approaches they require to be removed to some place where they will be protected from frost, for although

quite hardy, yet, when treated as pot plants, it is by no means wise to allow them to become frozen. The structure in which they are wintered should, however, be light, dry, and well ventilated, and no more artificial heat should be used than is absolutely necessary to secure them from severe weather. In private places Hydrangeas are often stewed away in winter under stages, and in other dark, out-of-the-way places. This is the worst possible practice, and plants so treated only produce good results by accident, as it were. The Hydrangea requires every possible ray of light during all stages of its growth, and even when dormant. About the first week in January is a good time to introduce a few plants into a comfortably warm house, provided it contains a bed of warm leaves or tan near the glass. This is the place on which to set the pots. Give a thorough soaking of warm water to the roots and they will speedily commence growth. When this has gone on for a few weeks, the bloom-buds will be visible on the tips of the shoots, and all suckers and other growth which does not contain any bloom should be removed in order that the energies of the plant may be concentrated in the production of large and finely-coloured heads of blossom. In a general sense, single heads or two shoots on a plant are the best; but in some cases, three or four shoots, as in the manner of the one illustrated (p. 387), may be suffered to remain. The plants should have every encouragement possible in the shape of a moist and genial atmosphere, and abundant supplies of liquid manure should be given. When ventilating, avoid all outgoing draughts of cold air, and at times of excessive sun-heat a little shade will be beneficial. Successional plants will, of course, be introduced as required, and in all respects receive similar treatment. A stake to each shoot will be necessary to prevent the breakage of the heavy heads of blossom. The Hydrangea can be grown to almost any size, but it is never more effective than when grown in small pots. As is now well known, the natural pink colour of the flowers may be changed to blue by an occasional watering with a weak solution of alum-water, or by potting in soil that contains an abundance of iron. H. B.

THE KITCHEN GARDEN.

4477.—**Making Asparagus beds.**—It is quite right to remove the soil and potstone to a depth of 2 feet, but do not waste that from the surface; it will do well for mixing with the other ingredients. I should not add salt with the soil, neither should I place manure deeper than 9 inches. If so, it will be lost entirely before the roots can reach it. At the bottom place any kind of vegetable refuse, partly decayed, retaining the better materials nearer the surface. The month of February would be a good time to make the bed. Planting is best done during the early part of April, while the weather is warm. The plants generally commence to grow at once. Not more than 3 inches of soil should be laid over the roots, finishing off with a layer of partly decayed manure and leaves, 2 inches thick. This acts as a mulching, retaining the moisture during the summer, and keeping the roots cool, inducing them to run freely in the new soil. Many persons make a mistake in not allowing sufficient space for the free development of the tops by planting the roots too thickly. The rows should be at least 18 inches apart, with not less than 15 inches of space from root to root in the rows. Three rows in one bed is ample. The outside row ought not to be nearer than 9 inches from the path. At no time should the path or alleys be disturbed. It is a senseless practice that many persons adopt of covering the beds with the soil dug from the paths. Not only does this plan allow the frost to injure the roots, but they must be severed in the digging, which produces a check to the plants which is best avoided. All that is needed when the tops turn brown in October is to cut them off close to the soil, clean off any weeds, and lay on a coating of partly-decayed manure, 2 inches thick, allowing it to remain all the winter, and early in April—or before, if the spring is a forward one—rake off the loose parts of the manure into the path, give the bed a soaking over; nothing more is then required. It would not be wise to cut Asparagus the first year after planting, even for three-year-old roots—I should

prefer to plant two-year-old roots—neither should cutting continue later than the end of June.—S. P.

RIDGE CUCUMBERS AND THEIR CULTURE.

The first week in May is quite soon enough to sow the seed of these, even when the plants can be raised in a greenhouse or frame, which is the only satisfactory way of getting the full benefit of one's labour, unless there are hand-lights to put over the seed as soon as it is sown. In that case the seed may be sown at the time I have stated; but, supposing there are no hand-lights available, I like to raise the plants in a cool greenhouse or frame, and plant them out the first week in June. Two plants of each in a 5-inch pot are enough. If there are more they will be weak, because overcrowded. It is also a mistake to prepare heaps of manure for them, unless there is enough to make into a hotbed and a frame is available to put on it. Good Ridge Cucumbers can be grown on level ground when the season is favourable, providing it is well manured and dug up a good spit deep a few weeks before planting time. It is a good plan to give the plants a little protection when they are first set

Cucumber "Greek or Athenian."

out—a large pot turned over them for a few hours during the day when the sun is very bright, and also at night, until the plants have grown too large for the pot to cover them. In exposed gardens the wind often does serious harm to the plants when they are quite young, therefore each one should be securely tied to a short stick as soon as planted out. Grown in this way, it is not often that the plants require any watering, unless the season should be very hot and dry. It is when they are perched on mounds that they require attention in the matter of watering. The Green Grecian or Athenian Ridge (here figured) is a capital hardy and free-bearing sort. The Gherkin is one largely grown by market men to supply pickle-makers. Stookwood Ridge is also another good and reliable kind. J.

4412.—**Woodlice v. Mushrooms.**—Persevere in trapping woodlice by laying small garden pots on their sides half-filled with Moss, and with a piece of Potato or Turnip at the bottom; or pieces of stale bread, bricks, &c., may be laid about; the woodlice are very fond creeping under such things. Pouring boiling water down by the sides of the walls where the creatures congregate is very useful, and also use a few teads.—G. S. S.

4414.—**Onion fly.**—The best means of protecting the Onions from the Onion-fly is to sow them in rows, not too thickly, so that they may require as little thinning as possible, and as soon as practicable earth up the hulks, so that the flies cannot lay their eggs on them. Soil saturated with paraffin-oil sprinkled among the plants, and afterwards well watered, has been found very useful after the plants were

attacked. When a plant is badly attacked it should be carefully removed with all the grubs and hurst, and the hole made by its removal filled with lime. After a bad attack give the ground a good dressing of gas-lime and fallow it.—G. S. S.

4468.—**Neglected Asparagus-beds.**—The beds must be in a bad state if it is necessary to take up the plants in order to clean the ground. The beds ought to be cleaned without disturbing the roots very much. If the roots must be lifted the spring is the best time to do it. When the beds are well prepared before planting, rich top-dressing, lightly forked, should suffice.—E. H.

Without the beds are badly infested with Couch Grass, Wild Convolvulus, or such-like deep rooting weeds, it is not necessary to disturb the roots in cleaning the beds. Pull out such weeds as Groundsel at once to prevent their seeding, and as soon as the tops of the Asparagus turn yellow they should be cut down close to the ground, the surface of the bed heeled and raked, repeating this as soon as more weeds appear. Spread over the surface of the beds a 2-inch covering of partly decayed stable-manure, leaving it there until the end of March or early in April, according to the season—early or late. Reke the roughest parts off the beds into the path on each side. Give the bed a dressing with common salt, enough to make it look white. This will act as a stimulant and a check to the growth of weeds also. Many persons dig the alleys between the beds, loyng the soil from the paths over the manure on the beds. This is altogether a wrong practice. Not only are the roots injured in the path, but an opportunity is given the frost to penetrate the sides of the bed. If the first shoots that appear next spring are of the size of the small finger, cutting a little will not harm the roots, but the general strength of the plants must be considered. If the growth is weak it would be unwise to cut from it for a year at least.—S. P.

It is not necessary to lift the plants in order to clean the beds; in fact, it would be injurious to the Asparagus so to do. It will soon be time to cut down the stems of the Asparagus-plants, and, when that is done, hoe up all the weeds and remove them with 2 inches or 3 inches of the surface-soil. When this has been done, give the beds a good dressing over the surface with decayed manure, and cover over the manure with an inch or two of fresh soil. This is generally taken from between the beds; but, if it is not available there, it may be obtained elsewhere. If the beds are worn out through bad management it would be far better to plant new beds with one-year-old plants in the spring; but the old beds, if treated as above, will bear a crop in the meantime.—J. D. E.

4163.—**Seed from Tomatoes.**—Let the fruit become dead-ripe on the plants, and when ready to drop rather than, scrape out the pulp and seeds into a tin sieve or strainer, and wash out the former under a water-tap. Spread the seeds on blotting-paper to dry, and store in paper packets in a dry place. There is no advantage in choosing very large fruits for seed, and small formed ones of moderate size are the best.—R. G. R.

For seed purposes save the finest fruits from the most prolific plants. Keep the fruit till dead-ripe, then rub out the seeds with a cloth.—E. H.

The White Wistaria—Amongst the shrubs that should be made note of for autumn planting is this Wistaria, which is not, however, new. But if not new it is very beautiful, and it is a pity that one does not meet with it more often, either planted by itself or as a contrast to the common type. Its racemes of flowers are produced freely, and are larger than those of the common Wistaria, whilst they are truly white, not a weak, watery kind of blue, as in many flowers called by the same name. When seen clambering over an arbour, out-house, or some such spot it is very charming. The only unfortunate feature about it is that it is a little tender. The double kind floriferous is a poor thing; the flowers double it is true, but of poor colour, and the racemes are not only short but very sparsely borne. Then there is the American Kidney Bean-tree (*W. frutescens*), another very interesting kind, but it is to the white variety alba that attention is especially directed.—O. T.

4477.—**Clematis attacked by mildew.**—The mildew has been caused by the check given by the drought. The Wistaria has had nothing to do with it. Dust with sulphur till the mildew disappears and give stimulents to the roots.—E. H.

FRUIT.

PROFITABLE FRUIT.

THIS year we have one of the most abundant crops of fruit on record, and doubtless the daily papers will teem with paragraphs as to the utter uselessness of the English cultivator trying to make a living by such a precarious venture, for they will point you to well-authenticated accounts of growers who have actually lost money by sending their fruit to market, as the rail charges and commission came to more than the articles realised. We are getting our full share of this sort of thing, and yet fruit culture goes ahead, for we may rest assured that a good deal of the imported fruit has of late returned nothing at all for the cultivators, and until we get better means of utilising the glut of fruit by drying, or preserving in some form or other, such things will continue to occur. The moral I wish to press home is this: Grew your fruit better in quality by timely thinning and high culture. Plums are a drug on our markets—Green Gages at 6d. per gallon, and common Plums, no bid at all for; yet on the same day fruiterers have come to me and asked for good large dessert Plums, and given 6d. per dozen to sell again, and other fruits are the same! Apples, ordinary samples, one can hardly get an offer of any sort for, but very fine samples realize 4s. to 5s. per bushel to sell again. Briefly, it is not quantity but quality that is needed, and only young trees, well cultivated, can give the kind of crop that will repay the necessary care. Hazard fruit growing don't and won't pay.

J. OROON, Gosport.

4417.—Caterpillars on bush fruits.—To prevent an attack next year you cannot do better than remove the soil from under the bushes to a depth of 3 inches in the course of the winter, and replace it with fresh soil. The Gooseberry sawfly grub buries itself in the ground and hibernates in chrysalis, from which in the spring sawflies will emerge and fly into the bushes and lay their eggs. The earth containing the chrysalides should be hurled or buried at least 6 inches below the surface. If everybody in a certain district would adopt this plan this insect would be almost exterminated; but if your neighbours do not take this precaution, the sawflies may fly from their gardens into yours. —O. S. S.

4485.—A Vine trouble.—Overcropping is the chief cause of your trouble. It is the old story, and one which it appears will be probably heard for all time, because people will not heed practical advice or profit by their own experience. Here is a case in which Vines twenty years old are expected to mature perfectly 60 bunches of Grapes, and because they refuse to do so the cultivator gets into trouble. At the same time, he admits that last year, with only 125 bunches there were a few shankers, and this year with two-thirds more the Vines have collapsed altogether. What else could anyone expect to happen? I can only hope for the benefit of our craft the lesson will not be lost. With regard to other matters referred to in the management, you appear to have acted wisely, except that you make no reference to having given the roots any water, which in this case, with the border raised considerably above the surrounding level and the long drought we have passed through, was absolutely necessary. Want of root moisture would aggravate the evil of overcropping. On the other hand, if they have had all the water they want the sudden collapse of the Vines only serves to further emphasise the error you have committed. The only thing you can do now is to relieve the Vines of the bunches as fast as you can, and if you have not given the border any water do so at once with no sparing hand.—J. C. C.

The cause of the bunches being so affected is owing to the Vines being too heavily cropped. It is a case of shanking, the breakdown occurring just at the colouring stage, which is usual in cases of shanking. Heavily-cropped Vines do not exhibit signs of failure until the colouring stage arrives; it is just during that extra strain that the trouble makes its appearance. It is a bad plan also to plant young Vines in an old border; the roots do not take kindly to the old soil. It is always the best way to make a new border when fresh Vines are planted, or if

It is not convenient to make a border entirely new, substantial holes should be taken out and new soil put in. In the present case, however, it seems it would have been wise to have removed all the soil, replacing it with new, not only for the benefit of the new Vines, but for the old ones as well. All that can be done at present is to cut off all worthless bunches, keep the shoots thin, so that the main leaves have sufficient room for development. Do not allow the lateral shoots to grow so thick as to crowd the main leaves, and make sure that the border is sufficiently moist that the roots do not suffer in consequence. If there is any trace of red-spider upon the leaves syringe them every evening with clean water applied with force. If the foliage is infested with thrips fumigate the house with Tobacco on three consecutive nights.—S. P.

4469.—Plantation of Raspberries.—Cut away all the old canes that have fruited at once, and reduce the young ones to not more than five per root. Clear the ground of all weeds, etc., and just prick in some well-decayed manure. Next year lay a good mulch of manure over the roots before the hot weather sets in, and fork it over in the autumn. Any canes that exceed 6 feet in height may be cut down to that point in the autumn or early spring.—B. C. R.

— Cut away all the old canes which have fruited this year at once, and thin out all the young canes which are weak, and then leaving four of the strongest canes to each stool. Dress heavily with good manure and fork it in, but as Raspberries are surface-rooting plants do not fork quite close up to the stools. After Christmas shorten back the canes left for fruiting to 4 feet or less, if the canes are grown without support. I have had as good crops on 3 feet canes as when left longer, but the canes were always well thinned out, so that the foliage was strong and healthy down to the bottom.—E. H.

— There will be no good crop next season unless the plants have made fair-sized canes this year. It is usual to remove all the canes from a plant but five or six, and these are cut down a little in the autumn or winter, when the plants get a good dressing of manure dug in between the rows. The surplus canes may be removed now, but it is better to do this in the summer to allow the fuller development of the remainder. In case of the plants being old and worn out, it may be desirable to make a new plantation. Trench and manure the ground well. Plant in November, 4 feet between the plants. They can be obtained from the sides of the old stools.—J. D. E.

— At the present time all that can be done is to remove all the canes that gave fruit this season, and all but sufficient of those of the current year's growth to cover the trellis on which they are trained in rows. The canes may stand 10 inches apart, and 8 inches if they are tied to stakes. By removing all the useless growth now instead of allowing it to remain to be cut out during the winter, those left will have so much better a chance to become well ripened before autumn, and in a much better condition to give fruit. If the soil within 2 feet of the Raspberries is exposed to the sun after the canes are thinned out and surplus ones removed, it is a good plan to apply a mulching of half-decayed manure to prevent the evaporation of moisture from the soil.—S. P.

4461.—Pollarding Apple-trees.—The effect of pollarding Apple-trees would be to canoe a great deal of young wood to start from the cut portions of the trees. If the shoots are too numerous remove some of them; these young growths will in three years bear good fruit again. If they have also cankered, the roots must be seen to; probably the land needs to be drained, and the roots may also have run down into an unsuitable sub-soil. In that case dig a trench 2 feet deep or more round the trees, and work underneath the roots, cutting through those that run downwards. The old soil should be taken away, and be replaced with good loam.—J. D. E.

— The best remedy with the old trees is to dig them up and burn them, planting young ones of approved kinds in their places. By good management it is possible to get full crops of fruit annually from young trees after the first year's growth. The varieties are so numerous now that it is a waste of time to allow old trees, and perhaps of worthless kinds, to encum-

ber the ground. Pollarding old trees is a waste of time; the roots have not sufficient vigour in them to push out the strong shoots necessary to do much good from cutting off the tops. The roots should be renovated with fresh soil and manure; this entails labour, and without, perhaps, much after-benefit.—S. P.

4384.—Strawberry border.—The preparation of a new Strawberry-had may be summed up in two words—viz., digging and manuring. Work the ground deeply and well, going to the depth of two, or, if possible, three, spad-lengths, but do not bury the fine surface-soil—keep it still uppermost, though if the topsoil is very light and the subsoil stiff or clayey, a small proportion of the latter may be advantageously brought up to the surface and mixed with the other. Add plenty of half-decayed stable or farmyard-manure, the coarser portions below and the finer near the surface. If the soil is light and sandy, on a gravel subsoil, a good layer of farmyard "muck" put in at a depth of 18 inches or so from the surface will do much good. On the other hand, should the soil be naturally stiff or clayey, a good heap of it should be burnt beforehand with wood or small coal, and the product be worked in the ground, the coarser siftings below and the finer above. If the ground is naturally wat a drain should be put in about 3 feet deep, but this need only be done if really necessary, as Strawberries like a moist situation. The best months to plant in are—If runners that have been kept over from the previous autumn in either store-beds or small pots can be had—April, May, and the early part of June. Otherwise you must wait until July, and then make use of runners of the current season. It is not too late yet to plant and obtain fruit next summer, especially if extra strong runners, or plants that were layered into small pots can be employed, but only a light crop can be expected now—the earlier the plants are got in the greater the yield of fruit the following season. Plant quite firmly, keep the crowns of the plants high, and water as required until established. The only subsequent treatment necessary is to keep all runners (except such as may be required for increase of stock) regularly out or pinched off, to keep the ground clear of weeds, and to apply a mulch of rather long stable-manure annually in March or the early part of April. This will help to keep the fruit clean, and should be lightly forked in towards the autumn, after the fruit is all off. Never disturb the surface of the bed at any other time, and as little as possible then.—B. C. R.

4482.—Hedge of Gooseberries.—I think you will be able to obtain what you require from Messrs. J. Chel and Sons, Lowfield Nurseries, Crawley. They make a specialty of cordon fruit-trees, and have the best stock of all kinds in this form I have seen.—B. C. R.

4456.—Best Strawberries.—Three of the best-flavoured Strawberries are undoubtedly British Queen, Dr. Hogg, and Keen's Seedling. Black Prince has also a very rich and distinct flavour, and it is early and very productive, but the fruit is small. The first named requires special soil and high and skilful culture, but Dr. Hogg and Keen's Seedling, the latter especially, will grow freely and crop heavily with ordinary treatment, and on almost any kind of soil.—B. C. R.

— Vicomtesse Herlesart de Thury is the best early Strawberry for flavour; it is a heavy cropper, but rather small as compared to such as Nehle, for instance, but its quality is superb, and it will succeed almost anywhere. Keen's Seedling is a really good flavoured sort, but not so hardy or so accommodating as the former as to soil and situation. Sir Joseph Paxton is a prodigious cropper, hardy constitution, and fairly good in flavour if eaten when thoroughly ripe. President is also a good variety. British Queen is also regarded as the finest flavoured sort in existence, but unfortunately it is rather fickle in its likes and dislikes as to soil. Dr. Hogg is supposed to be a good substitute for the former, and having a much better constitution it certainly is well worthy a place where British Queen does not succeed. Eleanor is a good late sort, but the latest of all is Waterloo, a free bearer and of good quality; the colour is, perhaps, somewhat objectionable, being a dull red, however, it is a desirable sort to grow owing to its lateness.—S. P.

AUTUMN TREATMENT OF RASPBERRIES.

RASPBERRIES, after the fruits are gathered, are often allowed to take their chance, but such treatment is not conducive to the formation of strong growths for next year's supply of fruit. No time after fruiting should be lost in giving the canes more room to develop by removing the old fruiting canes and useless suckers. There are often serious complaints as to Raspberries failing, the canes dwindling, the fruits being poor and only half the size they should be. This occurs in both heavy and light land. One reason is allowing the plants to occupy the same ground too long. On clay land the roots go down in search of food, only to find the sub-soil worse than the surface, and then decay of the fruiting canes occurs, no matter how carefully pruned and fed. On light soil much the same happens. There is no feeding material in the soil, and in this case heavy surface mulching must be given twice a year to keep the canes in a healthy state. Of course, all the mulching in the world does not get the plants into good condition once they have gone wrong. It is useless to feed Raspberries and to allow the old fruiting canes to remain on the plants for months after the fruit is gathered with a forest of suckers at the base. These suckers rob all the next season's fruiting canes of the nourishment which should go to build up a strong, hard, well-ripened cane the size of a walking-stick for next season's supply of fruit. At this date the old fruiting canes should be cut away, and only sufficient suckers left for the next season, choosing those that are strongest and in a healthy state. I only allow three or four to each stool. On weaker varieties five should be the maximum number, and these not too wide or far away from the original cane, as once they get wide of the old stool the plantation should be broken up and re-made on new land. Of course, if suckers are required with a view to getting canes for planting, more may be allowed. I have seen Raspberries occupy the same ground for twenty years, but this should not be, as it is impossible to get the best fruit or equal weight from canes in an impoverished condition. Removing the old ones need not occupy a long time, and those left should be tied to the old supports or wire fencing. The canes left for next season's fruiting should not be pruned in any way, but allowed free growth till late in the season, when they may be shortened back, but not to the required height, merely lightened of superfluous wood. At the final pruning in the early spring, cutting back to the height allowed may take place, as if pruned to the proper height in the autumn, the canes often die back lower down in severe weather. After the removal of old fruiting canes a good mulch of decayed manure should be placed over the roots, not dug or forked in; and on light gravelly soil there is no better mulch than manure from the cow-yard, as on hot, dry soils it keeps the roots cool and retains the moisture. This mulching should be given as soon after the fruit is gathered as possible to assist in building up strong canes for next season. G.

THE NEW ZEALAND FORGET-ME-NOT.

THIS is a native of New Zealand and was introduced many years ago, but one does not often see the plant in bloom. The heart-shaped leaves are of very large size, and on well-grown specimens measure fully a foot across. Above the foliage rises a flower-stem about 10 feet high, terminated by a dense cluster of flowers, each about the size of a sixpenny-piece, of a most beautiful turquoise-blue, shading off to pure white at the edges. It is a Borage-wort, and a near neighbour of the Forget-me-not. A very successful cultivator of the Mycoetidium sows seeds in September in a shallow pan, placing it in a cool, dark frame. In the following September the plants make their appearance, and are then removed to a cold greenhouse. In March they are potted singly into 2 1/2-inch pots in a mixture of loam and leaf-soil with a little silver-sand, and plunged in some Cocoa-nut-fibre in a cold frame. The plants are again potted in May, and at this potting some old Mushroom-bed is used with the soil. They are then replaced in the frame, plunged as before and shaded from the sun, the lights being always kept wide open. At the beginning of August

again pot them, this time into 8 1/2-inch pots, and remove them to their old quarters where they remain during the winter, being covered with mats on frosty nights. They commence to grow in the following March, and during the greater part of May and June will bloom. The New Zealand Forget-me-not requires much water when growing, and at the time they are throwing up their flower scapes a little manure-water helps them. Keep them free from green-fly which is death to them.

RULES FOR CORRESPONDENTS.

Questions.—Queries and answers are inserted in GARDENING free of charge if correspondents follow the rules here laid down for their guidance. All communications for insertion should be clearly and concisely written on one side of the paper only, and addressed to the Editors of GARDENING, 27, Southampton Street, Covent Garden, London. Letters on business should be sent to the Publishers. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Unanswered queries should be repeated. Correspondents should bear in mind that, as GARDENING has to be sent to press some time in advance of date, they cannot always be replied to in the issues immediately following the receipt of their communication.

Answers (which, with the exception of such as cannot well be classified, will be found in their different departments) should always bear the number and title placed against the query replied to, and our readers will greatly oblige us by advising, as far as their knowledge and observations permit, the correspondents who seek assistance. Conditions, soils, and means vary so infinitely that several answers to the same question may often be very useful, and those who reply would do well to mention the localities in which their experience is gained. Correspondents who refer to articles inserted in GARDENING should mention the number in which they appeared.

4600.—Vines in a cool-house.—Is it best to grow Vines in a cool-house in pots? If so, what size should the pots be?—M. A. R.

4601.—Nitrate of soda.—I wish to apply the above to my lawn, and wish to know when and in what form it should be applied?—R. H.

4602.—Packing Peaches.—I shall feel much obliged if anyone will kindly tell me the best way to pack Peaches and Neotines to send by post.—R. S.

4603.—Compost for the Oleander.—I should feel greatly obliged if someone will kindly tell me what compost will suit the Oleander best?—OLANDER.

4604.—Roses from cuttings.—I am told it is very easy to grow cuttings of Roses by striking them in bottles of water. Will someone tell me the process?—A.

4605.—Manuring ground.—Should artificial manure be put over ground before being dug for the winter, and if so what sort is recommended?—M. A. R.

4606.—Planting Strawberries.—I want to set out a new bed of Strawberries. What is the best time for planting, and at what distance apart? And what are the three best kinds?—ENQUIRER.

4607.—Treatment of Lilacs.—Lilac auratum and L. inodorum have not done well this year in pots. I intend to plant them out in the border. When should I do so—autumn, or spring?—G. S.

4608.—Tree Carnation-cuttings.—Will someone be kind enough to tell me how to strike some Tree Carnations for the greenhouse, and also for out-of-doors, or is it too late in the season?—E. C. I.

4609.—Cuttings of "Geraniums," "Fancies," &c.—Will someone please tell me when is the best time for taking cuttings of "Geraniums" and "Fancies"? And also of "Geeberries" and "Box"?—INQUIRER.

4610.—Roses for button-holes.—Will "J. C. C." and "P. U." kindly advise me as to the best dark-red variety of Rose, dwarf plants, not flowering, for button-holes, for pots in a cold greenhouse?—MANCHESTER.

4611.—Clematis Jackmanii.—Will anyone kindly tell me what is the best time to buy and plant out a Clematis Jackmanii? What month is the proper one for pruning it when well grown? Should it be pruned the first year?—ROMA.

4612.—Planting Clematis.—Will someone be kind enough to tell me the best time to plant Clematis, now or in spring, and where to obtain same? Also what kinds would be most suitable for front of house, north-east?—BROOKER.

4613.—Birch-wood ashes.—Would anyone kindly inform me if the ashes from burnt Birch-wooders are useful for potting "Geraniums," Wallflowers, and other soft-wooded plants in, and if so, what proportion to use to garden loam?—BIRCH.

4614.—Unhealthy Roses.—Will "J. C. C." or "B. G. R." kindly tell me what has affected my Rose-trees? They appear to have had a lot of soap-suds thrown over them, but that is not the case, and the leaves are shrivelling. Also the cause and cure?—FARO.

4615.—Myrobalan Plum.—I have seen this Plum favourably mentioned for bridges, and have sown one or two for it, but cannot get it, and all the catalogues I have looked at do not mention it. Does it go by any other name, or where can I get it?—BIRD.

4616.—Roses in beds.—Last year I planted two small beds of Roses. Will someone please tell me when is the time for pruning or cutting back, and how much I should cut off, and whether I should cut back the wood of last year, or the new growth of this year?—INQUIRER.

4617.—Lily of the Valley.—I have a lot of Lily of the Valley for forcing in winter, and intend planting them in a greenhouse heated by a hot-water pipe. Do they require a lot of manure as well, and when is the best time to move them into a hot-house?—EASTON.

4618.—Medlar and Roses.—In the Medlar a fairly quick-growing tree, or slow? Should one like to ask our friends "J. C. C." and "P. U." whether the thick liquid pumped up from a cow-pool is too strong for established Roses, and how frequently may I apply it? I am a believer in manure, but fear over-doing it.—BIRD.

4619.—Malmaleon Carnations.—I have a lot of young Malmaleon Carnations, and want them to flower in the winter. Would someone kindly tell me the best sort of soil to plant them in, and whether I should keep them in a Vine-house or in a Fernery? Both have a good deal of heat. Ought they to be near the glass?—EDWARDS.

4620.—Hiding a black paling.—I have an ugly black paling at the bottom of my garden which I should like to hide by covering it with some creeper; but it is much overshadowed by trees in my neighbour's garden. I shall be greatly obliged if you would suggest some plant that would grow in the spot under these circumstances?—E. BARN.

4621.—Begonias after flowering.—I have a few Begonias which have done flowering. I have put them under the glass, keeping the pots down on their sides, but they do not seem to dry off. They have been in that position about four weeks, yet some of the tops are still green. Have I done right, or wrong? Any information would be greatly obliged.—F. K.

4622.—Sea-weed as manure.—I shall feel obliged if someone will kindly inform me what are the properties of Sea-weed as manure, and whether it will take the heating properties of stable-manure? It is good for all garden produce—trees, shrubs, flowers, &c.? Living as I do by the sea I am able to obtain it in large quantities, and very cheaply.—FRANK LIGGERS.

4623.—An Ivy-leaved "Geranium."—I shall be glad if anyone will tell me the best way to treat a Pink Ivy-leaved "Geranium" in a cold greenhouse. It is now planted against the wall, and has a mass of bloom, 10 feet high, but has no new bloom, so straggling, and has a lot of dead wood under the green. Shall I cut it back to within 4 feet of the ground, and if so, when?—G. L. BATHUR.

4624.—Transplanting White Rocketes.—I shall be glad if anyone will kindly tell me if it is worth while to transplant a very thick border of White Rocketes? I sowed a packet of seed that autumn, and it has grown so strong and large this summer that the soil cannot be seen at all. It has not yet flowered, and as I am very ignorant in the matter I should be glad of advice.—MARY BARRER, Long-street, Manchester.

4625.—Rosa "Gindre Lyonalee."—An eager other Rosa I have a Gloire Lyonalee, six branches of which are pegged down, leaving nine or ten up-standing ones about 6 feet 6 inches high (the up-standing branches having grown since spring). The Rose is now well in April and May, and not since. Am I being the plant make too much wood? Should some be cut back? It is healthy and free from insects.—MICKLEBURN.

4626.—Laying out a kitchen garden.—I should be much obliged if someone would give instructions for laying out a kitchen garden, and the best advantages? The directions of the beds, the construction of the walks, with the best materials for edging them, the position of vegetables and fruits, such as Cuscuta, Rhubarb, Appareau, Raspberries, &c., are some of the points which would, I think, be of general interest to me and other readers.—LEONA PAULINE, M.L.C.S.

4627.—A span-roofed greenhouse.—Will someone have the goodness to give me the needed information to the following ones? I am about to put up a span-roofed greenhouse, 20 feet by 14 feet. It is to be built on ground at the back of a coach-house of which I have 10 feet below the base of the greenhouse. I desire to know how the heating of both may be best effected by the same boiler, and the best kind of the latter as concerns consumption of fuel.—J. A.

4628.—Cleaning Camellias.—I should feel much obliged for information on cleaning Camellias? I have six very large plants in tubs, which are very badly infested with what appears to be mealy-bug; the bark of the Camellias and the undersides of the leaves are completely covered with it. It is of a white colour, like mealy-bug, but on examining came I can find no insect resembling mealy-bug—i.e., same as I could find on a hardy plant. What can it be? And what remedy should I try to remove it?—CHRISTAL.

4629.—Treatment of Roses.—I have six Climbing Roses planted in a bed. (Gloire de Dijon is one; I do not know the names of the others). They are now in a house with Midge-bell Ferns; they have flowered well in the spring. The house is three-quarter span-roofed, and heated with hot-water pipes. They are free from green-fly. I wish to know what treatment should I give them from now to the time of flowering again in the spring? Do they require much water at this time? Should they have artificial heat? When should they be pruned, and in what manner?—CHRISTAL.

4630.—Management of pot-Roses.—Will someone kindly tell me the routine of management that pot-Roses require from year to year? I want mine to bloom in their natural season. I have a cold greenhouse facing due south. Last November I purchased two Teas, Catherine Marnet and Ferle de France. They are now in a house with Midge-bell Ferns; they have flowered well in the spring. The house is three-quarter span-roofed, and heated with hot-water pipes. They are free from green-fly. I wish to know what treatment should I give them from now to the time of flowering again in the spring? Do they require much water at this time? Should they have artificial heat? When should they be pruned, and in what manner?—CHRISTAL.

4631.—A small greenhouse.—I am having a small greenhouse erected 12 feet by 7 feet. The side facing north will consist of a wall about 7 feet high, from which will rise a span roof to 90 degs. and 100 degs. The blooms had little or no colour, and were borne on their weak stalks, which turned yellow a few inches from the bud. As soon as they had finished I plunged them in the ground in full exposure to the sun. They made no improvement in growth, and the blooms produced since were no better than before. Please tell me where I am at fault? I intend potting these Roses in September. What soil would be most suitable?—A. C. O., Tottenham.

4632.—A small greenhouse.—I am having a small greenhouse erected 12 feet by 7 feet. The side facing north will consist of a wall about 7 feet high, from which will rise a span roof to 90 degs. and 100 degs. The blooms had little or no colour, and were borne on their weak stalks, which turned yellow a few inches from the bud. As soon as they had finished I plunged them in the ground in full exposure to the sun. They made no improvement in growth, and the blooms produced since were no better than before. Please tell me where I am at fault? I intend potting these Roses in September. What soil would be most suitable?—A. C. O., Tottenham.

4633.—A small greenhouse.—I am having a small greenhouse erected 12 feet by 7 feet. The side facing north will consist of a wall about 7 feet high, from which will rise a span roof to 90 degs. and 100 degs. The blooms had little or no colour, and were borne on their weak stalks, which turned yellow a few inches from the bud. As soon as they had finished I plunged them in the ground in full exposure to the sun. They made no improvement in growth, and the blooms produced since were no better than before. Please tell me where I am at fault? I intend potting these Roses in September. What soil would be most suitable?—A. C. O., Tottenham.

4634.—A small greenhouse.—I am having a small greenhouse erected 12 feet by 7 feet. The side facing north will consist of a wall about 7 feet high, from which will rise a span roof to 90 degs. and 100 degs. The blooms had little or no colour, and were borne on their weak stalks, which turned yellow a few inches from the bud. As soon as they had finished I plunged them in the ground in full exposure to the sun. They made no improvement in growth, and the blooms produced since were no better than before. Please tell me where I am at fault? I intend potting these Roses in September. What soil would be most suitable?—A. C. O., Tottenham.

4635.—A small greenhouse.—I am having a small greenhouse erected 12 feet by 7 feet. The side facing north will consist of a wall about 7 feet high, from which will rise a span roof to 90 degs. and 100 degs. The blooms had little or no colour, and were borne on their weak stalks, which turned yellow a few inches from the bud. As soon as they had finished I plunged them in the ground in full exposure to the sun. They made no improvement in growth, and the blooms produced since were no better than before. Please tell me where I am at fault? I intend potting these Roses in September. What soil would be most suitable?—A. C. O., Tottenham.

If I have hit heated what would be best means of doing so? "Orchid Lover," whose interesting letter I read last week, speaks of a Syphon gas-stove. Would be kind enough to say if he found that economical and effective? Also what temperature be kept up during the winter? I would much like to follow in a reasonable, and should be therefor valued any further information he or any other correspondent could give!—J. PANCA.

To the following queries brief editorial replies are given; but readers are invited to give further answers should they be able to offer additional advice on the various subjects.

4632.—*Oxybaphus nyctagineus* (Umbrella Wort) (H. Stimmovdy).—This is the name of your plant which, although it was introduced many years before I was born, I have not seen in a living state for years. It is a native of the State of Missouri, in North America. It is a pretty plant, which thrives best in a sandy loam. The border must be well drained. I have been in the habit of protecting it in winter, but if it is a necessity or not I do not know.—J. J.

4633.—*Piper nigrum* (G. Souter, Glasgow).—The four specimens you send all appear to be species of the Pepper family, a genus comprising upwards of five hundred kinds, so that it is not to be wondered at that three of them I cannot name, but the one marked No. 2 appears to be a plant that I have grown as the Black Pepper (*P. nigrum*); but I have seen other kinds with the same name, but I suppose they are the same purpose economically. Send them to the director of the Royal Gardens, Kew, asking him to name them for you.—J. J.

4634.—The Kie-Kie of New Zealand.—J. Roberts asks if this plant is not a Pandanus? He has seen it wreathing the trees with a beautiful soft, and it is said to yield a very agreeable fruit. No, my friend; this is not a Pandanus, for I do not remember that the genus is represented in New Zealand; but it belongs to the same natural order. It is the plant called *Freyinotha Bankii*; it has long narrow leaves, which are spinulose; and the so-called fruits are the bracts which surround the male flowers; these are fleshy and pure-white. They have a delicious flavour, and are highly prized by the Maori, who call them *Tawera*. It is grown for the same purpose economically. Send them to the director of the Royal Gardens, Kew, asking him to name them for you.—J. J.

4635.—*Polygonum affine*—G. H. sends a specimen of this plant for a name, and it is less charmingly beautiful than I cannot help but notice it here. The leaves are about 8 inches long, somewhat oblong in shape, more or less wrinkled, minutely toothed at the edges, and pinnate. The flowers are produced in racemes, which are as long as the leaves, and of a bright rosy-red, becoming paler with age. It is a native of the Himalaya Mountains, where it is said to grow up to 14,000 feet elevation, consequently, it is quite hardy with us here; and I would specially recommend it to my friends and readers who have a bit of woodland in the country as a plant they should make attempts of in the Grass and other things.—J. J.

4636.—*Xylophylla latifolia*, J. Roberts is the name of the specimen you send with the remark, "It makes a very pretty plant, especially when, as now, it is in full flower all round the leaves." The above is its name, and it belongs to the Sparge-wort family; but whilst you are quite right about its making a very pretty plant, you are wrong about its flowering round the leaves, because these are plants that very seldom form any leaves—at least, in cultivation—and I never saw this plant with a leaf but once. This is formed on the tip of what you take to be a leaf. It is small, something like the *Chamaecyparis*. The organs you mistake, and very naturally, for leaves, are simply flattened branches, and it is around these flattened branches that your flowers are growing.—J. J.

4637.—Grubs eating leaves (*Heron*).—I cannot say what insect has eaten the leaves of your plants; there are so many that might have done so. The best way of finding out is to examine them at night. If the caterpillars of a moth are the culprits, it is not of much use dressing the ground, as the eggs are laid on the plants, and the caterpillars do not touch the ground. From the appearance of one of the leaves I am under the impression that the holes are caused by the rays of the sun being concentrated on certain parts by shining through drops of water, which causes withering and the death of the leaf at those parts; in consequence of the death of the leaf or the knocking out, causing the holes. I know that holes in leaves are at times caused in this manner, but I am uncertain if this is the case in the present instance.—O. S. S.

NAMES OF PLANTS AND FRUITS.

Any communications respecting plants or fruits sent to name should always accompany the parcel, which should be addressed to the Editor of GARDENING ILLUSTRATED, 37, Southampton-street, Strand, London, W.C.

Names of plants.—J. P. B.—*Coronilla* species apparently, but poor specimen.—*Nema*.—*Periploca graca*.—J. T. Marshall.—*Tradescantia discolor*.—*Asteron*.—*Camellia flavescens*.—K. Mitchell.—*Hippocrepis emarginata*.—Rose "Oleire de Dijon".—M. Maddison.—*Dogwood* (*Cornus*).—*H. G. H.*—*Wardian*, *Ramsay*.—1, Cannot name; 2, *Sedum Spaldii*; 3, *Sedum acre*; 4, *Inseuifolius*; 5, *Saxifraga hypnoides*; 6, *Inseuifolius*; 7, *Euphorbia parviflora*; 8 and 9, Cannot name; 10, *Podophyllum Emodi*. Another time please send better specimens, and only six of them.

Names of fruits.—H. Gamble.—Apples all too small to name.—J. M. G.—Apples: 1, *Empress Alexander*; 2, *Blenheim Orange*; 3, *Norfolk Seedling*; 4, *Peer Bourré d'Amantia*.—F. H.—Apples: 3, *Norfolk Seedling*; 6, *Five-veined Pippin*. Others we cannot name. Peas: 1, Not recognized; 2, *Williams' Bon Chrétien*.—B. Akkum.—Apple sent was decayed too much to recognize.—Box of Peas without name or address.—K. Oelshausen.—1, Not recognized; 2, *Winter Nette*; 3, *Brown Mar*.—H. G. H.—Peas: 1, *Williams' Bon Chrétien*; 2, *Esward*.—H. Carter.—Apple *Carlito Codlin*.—H. J. Sheppard.—Apples: 1, *Fearn's Pippin*; 2, *Empress Alexander*; 3, *Bymer*; 4, *Blenheim Orange*; 5, *Yorkshire Beauty*; 6, Not recognized; 7, *Cox's Orange Pippin*; 8, *Norfolk Seedling*. Peas not recognized.—J. J. Alfred.—Peas: *Bourré d'Amantia*.

TO CORRESPONDENTS.

We should be glad if readers would remember that we do not answer queries by post, and that we cannot undertake to forward letters to correspondents, or insert queries that do not contain the name and address of sender.

J. H.—Lift the Plum-trees in October.—G. A. Lambert.—Celery-ty; dust the leaves over with soot when they are wet with dew, and keep the roots of the plants well supplied with water.

BIRDS.

A reasonable note.—Now that the close season is well over the birdcatchers are busy, and young healthy birds can be purchased at a very reasonable rate which, with care, will make splendid songsters for next year. Cook Goldfinches at eightpence each, Linnets from fivepence to sixpence, Bullfinches from a shilling to eightpence, Siskins at the same price, Skylarks at a shilling, also Thrushes and Blackbirds. Cook Goldfinches have the shoulder black, in the hen it is brown; cook Linnets have the web of the flight feathers broadly white on one side, in the hen the white stripe is very narrow and does not touch the quill; cook Skylarks have the outer wing-feathers longer than in the hen, so that if the outer feather is drawn downwards to the end of the tail the shoulder still remains angular, whilst in the hen the shorter feather being drawn farther back, rounds the shoulder. Be careful to notice these points. Cook Thrushes you must catch yourself to tell the sex.—A. G. BUTLER.

NEW PHOTOGRAPHIC COMPETITION FOR 1893.

Owing to the early date at which our prizes were announced to be sent in this year there was not time to properly take many kinds of outdoor fruits, flowers, and vegetables; therefore we offer further prizes for these things, to be competed for during the present year; allowing till the end of November for the work.

Class I.—FLOWERING PLANTS.—A prize of FIVE GUINEAS to the sender of the best collection of photographs of flowering plants grown in the open air or under glass. This series may include flowering trees and shrubs of all sorts.

Class II.—BEST GARDEN FRUITS.—A prize of FIVE GUINEAS for the best collection of photographs of any of our good garden fruits: Grapes, Peaches, Apples, Pears, Plums, or any other fruit grown in Britain. Fruits should not be crowded in dishes if good and clear photographs are sought.

Class III.—BEST VEGETABLES.—A prize of FIVE GUINEAS for the best collection of photographs of best garden vegetables. The object of this is to get fair representations of the finest garden vegetables under the old genuine names. We do not want to exclude real novelties when they are shown. In all cases the name of the variety should be written on the back of the photograph.

Class IV.—AUTUMN FLOWERS AND LEAVES.—A prize of FIVE GUINEAS will be given for the best series of photographs of autumn flowers and leaves in the house in a suitable vase, table, or other kind of indoor decoration.

WHAT TO AVOID.—Cut flowers or plants should not be arranged in vases with patterns on them. Backgrounds should be plain, so as not to come into competition with the beautiful flowers. Figures of men or women, barrows, watering-pots, rakes, hoes, rollers, and other implements, iron railings, wires, or iron supports of any kind, labels, and all like objects should be omitted. Dwarf flowers are ineffective when taken directly from above. The camera should be brought low down for such. All photographs should be mounted singly, and not several on a card. The photographs should not be less in size than 5 inches by 4 inches. The following are the rules to be observed by all competitors.—

In any of the departments, if no collection of sufficient merit be sent in, no prize will be awarded. All competitors not winning a prize will for each photograph chosen receive the sum of half-a-guinea.

First.—The photographs may be of objects in the possession of either the sender or others; but the sources whence they are obtained must be stated, and none sent the copies of which is open to question. There is no limit as to number, and no fee to pay. The Editor is to have the right of selecting and publishing any of the chosen photographs. The photographs may be printed on any good paper that

shows the subjects clearly; but those on albumenized paper are preferred for engraving.

Second.—The name and address of the sender, together with the name and description of the object shown, should be plainly written in ink on the back of each photograph. This is very important.

Third.—All communications relating to the competition must be addressed to the Editor of GARDENING ILLUSTRATED, 37, Southampton-street, Strand, London, W.C., and the class for which the photographs are intended should be marked on the parcel, which must also be labelled "Photographic Competition." All competitors wishing their photographs returned, if not successful, must enclose postage stamps of sufficient value for that purpose.

Thoroughly well built of best seasoned red deal, glazed with 21 oz. glass, painted 4 coats. Heated with Saddle boiler and 4-in. H. piping. Fixed complete within 200 miles. Brick-work excepted. Carriage paid. 30 x 12, £31; with Heating Apparatus, £43; 40 x 12, £48; with Heating Apparatus, £55. Could be erected in few days.

HARDY BRUIN & CO., LEICESTER.

A. OVEREND F.R.H.S. & CO., THE GENUINE HORTICULTURAL BUILDERS,

Supply Greenhouses, large or small, from 50s. to any amount, as cheap as any advertised at 25 per cent. better quality and finish.

ILLUSTRATED PRICE LISTS FREE. INSPECTION INVITED. WEST GREEN WORKS, TOTTENHAM, LONDON, N.

WHY LOSE YOUR PLANTS IN WINTER? New Apparatus for Gas or Oil (Kogd.) HEATS WITH ONE FISH-TAIL BURNER. Price 35s.

G. SHREWSBURY, STATION ROAD, CAMBERWELL, S.E.

GARDEN NECESSARIES.—Virgin Cork, 12 lb., 17s.; 56 lb., 10s.; 23 lb., 5s. 6d.; 14 lb., 3s. Bamboo canes, 4 feet, 3s. per 100. Tobacco-paper, strong, 1s. per lb. Vapour cones, 1s., 1s., and 1s. 6d. each. Raffles, 1s. per lb. Cocoa-fibre, 1d. each. Manures, Man, Garden Salts and Labels, Sand, Peat, &c. Price list on application.—WATSON & SQUILL, 90, Lower Thames-street, London, E.C.4.

HEXAGON NETTING, 90 mesh to square foot, warp and fly proof, 4d. square yard, any width. Octagon shading net, 54 inches wide, 6d. yard. Garden and Tennis Nets, 4 yards wide, 8d. yard.—W. CULLINGFORD, 31, Eastern-road, Platford.

SOUTH DOWN SHEEP.—Pure-bred SHEEP, from flocks of best blood, for stocking or exportation. A number of good rams.—Address, BAILIFF, Home Farm, Gravetye, East Grinstead Sussex. Inspection invited.

PEDIGREE SUSSEX CATTLE (Gravetye & Hard).—The Sussex cattle are growing steadily in public favour, both in this country and in America, where a few years ago a steer of this breed won the first honour in the stock test at Chicago. Choice Doves and Young Stock of the best blood for sale. This herd never got up for show, but kept under the most natural conditions possible. Inspectors, East Grinstead, Sussex.

TAMWORTH RED PIGS.—For Sale, Sows, 1 Year and Young Boars. Pure pedigree bred. Recommended as good bacon pigs; also for crossing.—Particulars from BAILIFF, Home Farm, Gravetye Manor, East Grinstead, Sussex.

NOW DISENGAGED, a practical GARDENER, prepared to take charge of a gentleman's estate; thoroughly understanding gardening indoors and outdoors, also stock farming. Exceptional references.—Apply to EDITOR, The Garden, Southampton-street, Strand, London.

SITUATION WANTED as Head Working Gardener of good Single-handed, where help is given. Good experience in herbaceous plants, Roses, Carnations, &c. &c. married, no family, good character. A. HIFD, 10, Blackfriars-road, London, E.C.4, Routhend-on-Sea Essex.

LILIUMS FOR EARLY FORCING.

TAKEN as a whole, the genus *Lilium* affords but few species or varieties that may be forced very early into bloom, and yet be regarded as profitable from a commercial point of view. To be profitable at all they must be so at the first attempt, simply because when forced early into flower the bulbs suffer so much in consequence as to be of little or no use ever after, and particularly does this apply to those belonging to the longiflorum group. All those who take them in hand, therefore, should bear this in mind from the beginning and act accordingly, doing their best to make the best of them in the first season. All Lilies which may be forced, however, do not behave quite so badly as those of the longiflorum section, and of none is this so true as the fine old Lily so frequently seen in gardens almost everywhere throughout the country—I mean the Madonna Lily (*L. candidum*). This grand old-fashioned flower may, provided disease keeps away from it, not only be forced into flower quite early in the year, but, what is more, it may later on be planted again in the open ground, and there left for a season or two to recover itself and once more be forced, and with good treatment in the interval, prove quite as satisfactory as when originally forced. It must be stated, however, that the measure of success to be hereafter attained will greatly depend upon the treatment the bulbs receive after they have flowered when first forced. To the commercial man—the grower for market—whose business it may be to cultivate for the flowers alone, this being able to utilize the bulbs again after a season or so of rest should be, as it is in some few instances known to the writer, a subject for serious consideration, for herein lies much of their value. Growers of bulbous plants, and in particular those who go in for early forcing and have to purchase year after year fresh supplies of bulbs either from home growers or from Continental sources, know something of the uncertainty and risk attendant thereon, and how narrow the margin of actual profit is when the flowering is completed. Such men as these will not be slow to recognize the

VALUE OF A BULB that may be grown by every one of them in ordinary garden soil, and one, moreover, that will provide enough bulbs of fine quality for future use without having one again to pay the top price of the market. Now this is exactly what may be done with *Lilium candidum*—a Lily of easy culture in most gardens, and in good loamy soil producing wonderfully firm, solid bulbs, the equal of which rarely ever reach us from Continental importations. These latter are frequently loose and generally fishy to the touch, too light also in proportion to their bulk, and produce results in a like degree as a consequence. Home-grown bulbs of this Lily, on the other hand, are distinctly solid and heavy, with the scales closely imbricated; these are the bulbs to do good service, and those interested should use their best endeavours to secure them. The present is a capital time for obtaining them, as it is of importance when intended for forcing that they

should be potted while dormant, and before the new radical leaves from the bulb. Having secured the supply of bulbs, get them into the soil with as little delay as possible. If, as I have said before, they are grown for the flowers alone, I would suggest putting several bulbs, according to their size, into 10-inch pots rather than adopting the usual method of planting the bulbs singly in 6-inch or 8-inch pots. With the soil fairly charged with roots there is really very little opportunity in this particular case for the bulb to develop itself, an item of importance where the well-being of the future bulb receives consideration. Apart from this, the above size of pots afford but very little depth, besides being often troublesome by the top-heaviness. Five or six bulbs in a 10-inch pot, or larger if in stock, have a much better chance, because while affording a much greater depth of soil, abundant room may still easily remain for giving a thorough watering when necessary, a matter often very imperfectly performed when small pots are employed. This, then, I hold to be an advantage to the bulbs, helpful in the production of a good crop of flowers, and a decided saving of labour, as well as satisfaction that the work so far as possible is properly performed. The

POTTING MATERIAL for this Lily need be no elaborate mixture, good loam constituting the bulk. Very little or no manure need be used; indeed, the crop is much more likely to keep free of disease where none is employed. Add a little sharp sand, or old mortar rubbish or charcoal will do equally well, potting rather firmly and covering the bulbs an inch deep with soil. When potted plunge the pots in coal ashes, and for the time being withhold water from them entirely; but when the radical leaves display signs of renewed activity they may receive light showers occasionally, never allowing the soil to become saturated. The plunging material, I should have stated, should only just hide the pots from view; if employed at a greater depth it has a tendency to draw and weaken the radical leaves, and these when taken from the ashes are frequently broken or injured and sometimes lost. Where radical leaves spring from the bulb it is important that they should be preserved and retained, as they materially assist in the production and development of the roots. This fact is amply demonstrated by those bulbs of this Lily which, from some cause or other, do not send forth these leaves in due course, and invariably it will be found that the roots in these instances are inferior and root-formation sluggish generally. Some people in starting this Lily for forcing or pot culture do not in the first instance cover the bulbs with soil at all, but are content merely to place the bulb on the surface of the soil, and when about to start into growth to cover them with soil. I fail to see, however, the wisdom of thus unnaturally exposing a bulb in this manner to all the varying influences of temperature and climate to which we are accustomed just at the moment when we are expecting it to push forth growth, and when the keeping of the bulb in a uniformly plump condition should be one of our chief views to assist in the speedy formation of roots. The Madonna Lily, it should be

remembered, does not produce stem roots, so that there is nothing to be gained by thus exposing the bulbs, and I strongly urge not only covering the bulbs with soil, but adding a little covering of the plunging material also. Later on in the year, say early in November, when a fair amount of roots has been produced, the whole hatch may be moved into a cold pit or frame, giving plenty of air day and night for the present. The end of the year will be quite soon enough to introduce it into heat, and let this at first be gradual, as this Lily is very sensitive to artificial heat, and a temperature too warm will have the effect of producing a weak, puny growth. A temperature of 50 degs. to 55 degs. will suit well, using no more water at the roots than is absolutely necessary.

IN FORCING this Lily, studiously avoid the use of the syringe over the plants; damp the floor or other available surfaces early in the day while the ventilators are still open, avoiding a close, stuffy temperature for one the reverse. It is undoubtedly well known that in wet seasons this Lily in the open ground is very susceptible to a disease which ruins the crop in three or four days, and it is equally so under glass if the use of the syringe is freely indulged in and the atmosphere overlaid with moisture. If kept moist—but not wet—at the root and a comparatively dry, warm atmosphere maintained, there will be no need to fear disease in the early forcing of this Lily, which, though a commonplace plant in many gardens, is undoubtedly one of the best of its race, and still the purest and most chaste of all Lilies. Yet another Lily specially suited for early forcing is the new well-known

EASTER BERMOUDA LILY (*Lilium longiflorum* Harris), a kind now grown in immense quantities for market as well as for private use. During the last ten years enormous quantities have been sent to this country from America, where it undoubtedly finds a home remarkably suited to its free growth and full development. It is, perhaps, even more in demand than the species just noted, being very serviceable as a pot plant for general decorative purposes, as well as popular among out-flowers in many and various ways. It may also be subjected to hard forcing when occasion requires, the primary consideration being to produce a fine spike in the first season, because when once subjected to forcing, the bulbs are of little value after. Probably the climate which produces it so plentifully and of such quality may have the effect of restoring it again to its former healthful vigor, but certain it is that in England at least the trial is so much waste time. I have repeatedly tried to reanimate the bulbs of this kind, but have never had the slightest success, and eventually had to consign them to the rubbish-heap as worthless. The only service they ever rendered was when I turned them out of pots as soon as their flowering was over and roughly planted them in an out-of-the-way corner, where they had no attention whatever. Under this treatment many produced another spike of bloom, and though small, bearing sometimes three flowers, they were, nevertheless, valuable, particularly enough these flowers, because wanted just at the time, realized even more in the market than many of the very

superior flowers that had been forced into bloom. But while a few flowered thus and were useful enough at the time, the bulk of the batch was only represented by shattered fragments. The earliest consignments have already arrived, and the herbs should be obtained at once and potted without delay. In the purchasing of this Lily little or no disappointment should ensue, inasmuch as the bulbs are generally offered in sizes of so many inches' circumference, which gives the purchaser an opportunity that may be repeated with other things to the better satisfaction of all concerned. It generally happens with most imported bulbs that the best—which in this case may also mean the largest—are the cheapest, but on more than one occasion with this Lily I have proved the contrary to be the fact. For example, let us take three sizes as usually offered, these having a circumference of 5 inches to 7 inches, those of 7 inches to 9 inches, and those of 9 inches to 11 inches, the last, of course, being simply magnificent in point of size. What I wish to point out, however, is this—that if anyone required to spend say £3 or £10, and his object was flowers for market, I should unhesitatingly advise him to purchase medium-sized bulbs, because he would obtain more flowers for his money than if he purchased the largest bulbs, for it should be remembered that because giant bulbs it does not follow that this increase of size means increase of flowers to the same extent; and another thing, very large flowers are not so much in demand as medium ones, because these latter are suited to a larger number of buyers.

AS POT PLANTS again, those of medium height are decidedly the most useful. Plants of 6 feet or more high, and with from eight to a dozen flowers, are excellent in many floral groups and duly appreciated. These are also very imposing for home decoration, but, regarded all round, those of medium size are at once more serviceable and far more easily accommodated and managed. This Lily delights in a fairly rich soil, and produces abundance of large roots very quickly when potted; indeed, I have had the pots almost fully charged with roots in three weeks after potting about the middle of August. There is a lesson in this their eagerness to start root which should not be lost sight of, particularly as inquiries are at times made concerning malformed flowers. These Lilies are grown in a much hotter country than our own, hence mature earlier, and are ready to recommence growth in proportion. To keep these bulbs dry and out of the soil till early the end of the year is, therefore, a great mistake. It is not unlikely that such a course would tend to malformation, though half-a-dozen other things may lead up to similar results.

SECURE YOUR STOCK OF BULBS EARLY, then, and let them root in proper season, as is the forcing of Lilies, or, indeed, any other plants, a full complement of roots is one of the most important items to success. In potting use pots in proportion to the bulbs, giving at the original potting the sized pot in which it is intended to flower them, subsequent potting being of little or no good, but frequently the reverse. Pot firmly and plunge in coal-ashes, covering 6 inches deep. A few weeks in the ashes will suffice, for the bulbs are just as eager to produce top-growth as they are roots; and when the points show above the ashes remove them at once to a cold pit, in which they may be darkened for a while and by degrees inured to the light. Give air abundantly for the present, as they make very rapid growth even with frame protection, while a close, stuffy atmosphere will also conduce to the more rapid increase of green-fly, a veritable foe to this particular Lily; indeed, it is almost impossible to grow it unless the fly, and if this gets the upper hand it is difficult to get rid of it. In consequence of the attacks of this insect pest I prefer always to pot this Lily singly. I have found that dipping the plants is the best means of eradicating them, inasmuch as the fly congregates in the top of the plant, and in this position is more difficult to kill by fumigation, but it cannot escape when it comes to dipping the plants. The most effectual way is to fumigate thoroughly in the evening, which clears off any insects existing on the exposed leaves and stems, and follow in the morning by dipping the tops of the plants in Tobacco-water, or in soap and Quassia; this will have the effect of

leg out all those existing in the closely imbricated heart-leaves. Unless some such means are adopted, fumigation alone becomes a very serious expense where Lilies are grown in quantity. When growth is completed and the huge ribs on the summit of the stem, there is no longer a hiding-place for the fly, and ordinary fumigation will then suffice.

GARDEN WORK.*

Conservatory.

The days are visibly shortening, and the sun, though hot at times, is losing its power. No shading will be required now; but the ventilation should be ample and free, both night and day. This being the season when the plants which have been placed outside to ripen up growth are housed again, this night ventilation is very important to prevent the plants coming from the open air receiving a shock and losing their foliage. This is especially necessary in the case of hard-wooded plants. As a rule often lose foliage which might be retained if the conditions of housing times were made more suitable. Watering also requires more care till the plants settle down under the changed conditions. What a harm there is about a collection of plants! But so do they well require a light cool-house, where the plants can have careful treatment, without the presence of those soft-wooded subjects which always require a good deal of moisture, and a damper condition of the atmosphere than is good for them. If plants must be grown in a mixed collection of plants, only a few varieties, such as *Hymenocallis*, *Wilmoreana*, *Caveddahi*, and *ventricosa*, should be kept. The *ventricosa* section are very handsome, and are not so difficult to manage as the triflorus and other hard-wooded sorts. Especially are very useful winter-flowering plants, and should now be under cover. They will bear a close, warm atmosphere better than most. Good specimens of the *Encalyptus* (Blue Gem) form pretty good subjects; the blue glaucous plants come out well in the conservatory. There seems to be springing up a demand for these for room-plants, there being an impression abroad that they have some effect in warding off disease. Whether they have or not, the idea of growing a *Gum-rose* or two indoors is not a bad one. Winter-blooming stuff, such as *Cineraria*, *Primula*, and *Cyclamens*, should here very free ventilation night and day to make the plants vigorous yet sturdy. Hardy winter is a valuable principle in a winter-blooming plant. Keep *Arum Liliacis*, *Salvia*, *Eupatorium*, and such subjects out as long as it is safe to do so; but they must not be exposed to frost. Roses intended for forcing should be pruned and top-dressed. As far as possible prune so as to leave a single stem, or two inches if not a bud or two strongest bloomers. The same principle is applicable to *Tra* Roses. A plant all soft-wood shoots is not of much use for forcing, as the blooms must be small and poor. This out the summer-flowering climbers, and give encouragement to those plants which are effective in winter.

Stove.

Do not let *Poinsettias* get pot-bound before shifting them on, or the bottom-leaves will fall. These plants should have a little artificial heat now regularly. Therefore, they must be moved now from cold pits. The same remark applies to most of the soft-wooded stove-plants, which are better kept in low pits or frames during summer. Referring again for a moment to the *Poinsettia*, what a grand plant this makes planted against a wall in a house where heat is used in winter! Where the trunks of scabred beards are required for cutting, two or three strong plants set out against a wall in a light-house where a temperature of 50 degs is kept up in winter will yield hundreds of heads for the knife to deal with. This plant might be associated with *Euphorbia jasquiniflora*, both of which are splendid plants against a wall in winter, the young shoots being trained to wires. A drier atmosphere should be maintained now, but the change should be very gradual, or the plants will be attacked by insects. The work of destroying insects must be incessant. It is perfectly true that when the conditions of growth are favourable, insects do not get so much trouble. Let a check come from any cause, and insects become more numerous, and soon begin to swarm, and no plant can be badly attacked with insects without serious injury being done. Therefore, in reducing the atmospheric moisture to meet the shortening days allowance must be made for the drying effects of fire-heat. In a general way when fires are first lighted it is quite possible that injury may be done by overheating. Some persons cannot make a small, steady fire that will just circulate the quantity of heat required and no more.

Hard-wooded Plants.

As soon as the house for these has been cleaned or painted and made ready, all New Holland plants, *Cape Haths*, and other hard-wooded plants should be placed under cover. Make the change for them as gradual as possible by leaving on air night and day so long as the weather will permit. If time permits the staking and tying may be done now; but very frequently this work has to be postponed till the bad weather comes in winter.

Zonale for Winter-blooming.

Discontinue picking off flower-buds, and before heavy rains come the plants should be placed under cover. It is not likely much will be done with these in a lower temperature than 55 degs. to 65 degs., and the house must be light and dry. I have had *F. V. Russell* very good planted out in a border in a light-house, and any good free-blooming variety, such as *Wright*, *Brighton Gem*, or *Henry Jacoby*, will do well planted out in a warm-house. One of the most useful plants to grow in quantity for the production of cut-flowers in winter is the *try-leaved variety*, *Mme. Crocote*. The flowers are soft-pink, semi-double, and have long stalks. It grows and flowers freely, and is one of the best winter bloomers.

* In cold or northern districts the operations referred to under "Garden Work" may be done from ten days to a fortnight later than is here indicated, with equally good results.

Bulbs for Forcing.

A good many of the Roman Hyacinths will now be potted and making roots outside plunged in Cocoa-nut-fibre. Freesia will be coming on without plunging in cold frame or pit, neither will require much water for the present. One good watering settles the soil, but when plunged the bulbs get moisture enough for a time, at any rate, from natural sources. Hyacinths, early Tulips, Narcissus, Squills, Bermuda and Old White Lilies should be potted now and plunged to cold pits.

Chrysanthemums.

Where large numbers of Chrysanthemums are grown the work will be increased. If the plants lack support the leaves will lose colour, and if the disbudbing is not promptly done the buds which are just being selected may perish for lack of nutriment.

Window Gardening.

The most brilliant plant for the room garden just now is the Starborough Lily, and its culture is simplicity itself. When a good potful of bulbs has been secured do not be in a hurry to divide. Let the bulbs grow, and then place outside, and there will be plenty of blooms.

Outdoor Garden.

The rare ones opportunity for the *Ornithogalum* layer, which now look strong and healthy, and the soil will soon be in condition for removal. There is a manifest advantage in early layering, and there is also an advantage in moist soil in using a light gritty compost to surround the plants, and to hold the layered shoots are to be pegged. The beds to receive the layers should be got ready, and in turning over and intermixing the soil look closely for wireworms. A dressing of soot will be useful for all the *Dianthus* family. If not already done the time of last early-budded Rose should be removed. Considering the character of the season, the buds have taken fairly well. There has, of course, in consequence of the drought been a great loss among Standard Briers, and Standard Roses will be dear this coming season. Intending planters will do well to place their orders in good time, as it is likely the best plants will go early. The late-started Briers may be bodded any time this month, the sooner the better, of course; but at the usual season of budding many of the Briers were unrootable, but the growth has since been rapid. The leaves of the *Linas* and other early trees are falling, reminding us that autumn is near. Outings of tender plants of which more stock is required should be taken at once. "Geraniums" should be kept outside yet. Get a good stock of Yellow and White Marguerites, spring-stuff does not get large enough to make an early display. Many hardy things may be rooted from cuttings, preferably under glass. The White-leaved *Clematis* redolens makes a good edging, and being perfectly hardy may be used in ornamental gardening in the place of Box-cuttings if the ends of the shoots will root during the autumn under glass. *Pentstemon*, *Tufted* and other *Fenelles*, will root now with certainty.

Fruit Garden.

Apples and Pears were well cultivated here, I think, never been better in season. There will, I dream, be plenty of small rubbish; but this is the fault of the system, or, rather, want of system, adopted in orchard management. Some of the late sorts will be fit to gather earlier this year, but it will be well to wait till the fruit are perfectly fit for gathering before removing them from the trees. Shrivelled Apples are out of much use, and Apples gathered before they are quite ripe are sure to shrivel. Court-Pendo Plat is a bright-coloured fruit, and keeps well if allowed to hang till the last moment, but if taken from the tree too early nothing can prevent shrivelling. This Apple is rarely in good condition when exposed on shelves in the fruit-room; but packed in barrels and boxes in a cool room it will come out right next January, or later if required. The best way to pack late Apples and Pears—the best specimens, at any rate—is to wrap each fruit in tissue paper and pack in layers in barrels. These may often be purchased cheaply from the grocers and provision dealers of different towns, and if taken care of they will last many years. Root-pruning, should any be necessary, may begin very shortly. In capable hands the work may begin now, doing those trees first where the wood is getting firm. Work of this kind may be done earlier this year. This matter has been so often referred to it is hardly necessary to go into details further than to say that severe pruning of either root or branch I do not recommend. When carefully done, root-pruning is the proper means for checking luxuriant growth, and inducing a more healthy habit. Very plants intended for forcing free from runners, and stand the plants thickly on beds of ashes.

Vegetable Garden.

Late-planted Calery should have liquid-manure twice a week, not a mere dribble, but a good honest soak. The longer nights and the dew will cause rapid growth if the roots are kept moist. The Early Kale, of course, sowed, sowed, and succulent crops will soon be ready for that operation. The work should be done when everything is dry, and the soil must not be allowed to penetrate the centre of the plant. Draw the leaves up carefully, and secure them with a string of netting before applying the soil. Press the soil firmly round the plants with the hands at the top, as this will keep out the wet and facilitate the blanching. Young seedlings of *Onions*, *Sprouts*, *Potatoes*, *Chardflowers*, &c. must be kept from weeds. Potatoes are fairly free from disease so far as the tubers are concerned, but I have noticed symptoms of disease in the foliage some days ago; but, on the whole, there is less disease this than has been seen for some years. Up to the present *Tomatoes* in the open air are quite free from disease; at least, I have seen none, and the crop is ripening up well, and most, on the whole, have been a paying crop, though the prices have been ruled low. Broccoli plants in pots set out now in a house where fire-heat can be used when required will set some fruit during the autumn, and will be right for fruiting early in spring. Plant a good breadth of Cabbages, and fill in the spare south borders with Lettuces and Endives. Sow Turnip Radishes, and keep well supplied with water. Clear off all old stems and dead leaves from Globe Artichokes. The young plantations will be bearing now. Liquid-manure will help them now. Strip the seeds from *Asparagus-plants* if they are very exhausted, and will give a crop of trouble in the future if they ripen and drop about. E. HOUDAY.

Work in the Town Garden.

The weather still remains extremely dry, and plants of all kinds under glass, as well as many of those outside, require copious supplies of water, though in many cases not so much now that they are going to rest as two or three months ago. In a season like the present, what may be termed "dry weather" flowers are alone of any use in the garden, and some of the most useful are the common "Geraniums," Petunias, Verbeas (where growing in deep and rich soil), Galliarides, Gesanias, Phlox Drummond, the French and African Marigolds, and two or three more. I do not think I have ever seen the Soapdragons (Antirrhinum) doing better. They have flowered most profusely, and at a low height than usual. I have a quantity of the pure white and yellow-flowered forms, and find them not only of the greatest value from a decorative point of view, but unsurpassed as cut flowers, being so very pure in colour, and lasting so long a time in beauty. It is worth while remembering that chelidonium varieties are easily increased and perpetuated by means of cuttings, inserted new in sandy soil under a frame or handlight, as well as by seed. Gladioli, too, are flowering extremely well, and so are plants of a succulent nature, such as the Mesembryanthemum (by the way, what a gem is tricolor in this season), the brilliantly-hued Portulaca, &c. Michaelmas Daisy

THE COMING WEEK'S WORK.

Extracts from a garden diary from September 16th to September 23rd.

Have just had the heating apparatus overhauled and put in condition for use. In one case the fire-bars had given way; another, boiler had never been properly set, the flues both at the sides and on the top were too small. It is sometimes difficult to get a bricklayer who really understands setting a boiler, and one of the mistakes they make is to have the flues too small, that is difficult to keep the draught clear. No flue should be less than 2 inches wide; 7 inches would be better for large boilers. The boiler in question has been uncovered and the flues altered, and I am persuaded the cost will be saved in fuel, and in the greater ease with which the flues can be cleaned with hot and brush. Another matter will be brightening of the chimney. A few chimneys cannot be recommended. The fire wants space to do its work, and a lofty chimney where the boiler is large is a necessity. No chimney should be less than 15 feet; several feet higher will be better. Moved a lot of late-potted Tuberoses which have been grown cool up to the present into a house where fire-heat is used to give size to the blooms, which are now

Solenum have set a good crop of berries; but those plants which I turned out early enough to make their blooms outside have set the best. To get plenty of berries ripe enough for autumn work they should be placed outside by the end of June, and should stand thickly in an open situation. I have just been doing a little budding. A few Dwarf Blazes and Minette had been left till now; I suppose chiefly because they had not made much growth and the bark did not work well. However, the bark works freely now, and I have no doubt the buds will take well. Potted up a number of Mrs. Sabine Pinks for forcing. This plant forces well, and the flowers are valuable. I generally depend upon young plants, but this year I have about a hundred of last year's plants in pots for early blooming. A rich top-dressing will be given, and the plants will be helped with liquid-manure.

CHRYSANTHEMUMS.

EARLY-FLOWERING CHRYSANTHEMUMS.

DURING recent years, one has heard almost as much of the early-flowering Chrysanthemum as the big, highly-fed giants that are placed on exhibition tables in murky November. This is a healthy taste, as the early-flowering kinds, so-called for the reason they bloom in September and early October, are not pampered, nor is mere size arrived at in the individual flower, as if size signified perfection. Much has been written in previous issues of GARDENING concerning the culture of Chrysanthemums, whether in bloom in September or December, so that the present notes will be devoted to pointing out a few of the newer kinds not grown by everyone. The majority of the early-flowering varieties belong to the Japanese class, and this is a pleasant fact to record, as this section of old was chiefly composed of the Pompons, such as Roh, very pretty it is true, but far eclipsed by the later acquisitions that rival in beauty of colouring and expression the finest November kinds. Amateurs who cannot boast even of a greenhouse can have them with little expense, and, if the weather is at all favourable, enjoy them in the open, keeping court with the many other things that bloom at the same time. Of course, the queen of all early-flowering Chrysanthemums is Mme. Desgranges and its varieties, which are too common to describe. I must point out, however, that they should not be over looked, as they are very beautiful, extremely free, and easy to grow. A small bed of Mme. Desgrange makes a charming show of colour, and the flowers are useful to cut for the house. The danger in getting novelties is that one is apt to lose one's head over them, and purchase things far inferior to older acquisitions that cost half the price. One of the best of all the more recent varieties is M. Gustave Grunerwald, which may be described as a pink-flowered Mme. Desgranges. It has all the good qualities of the type, the flowers large, and very delicate pink, which passes to white with age. It is as yet rather expensive, but will get cheap in time. Madame G. C. de Brialle is a fine variety; the flowers large, of a creamy-white colour, and dark centre. Albert Chanson is of merit; the flowers golden-yellow in colour, with stripes of rich crimson. Alfred Fleuret is a charming kind, the flowers thin, but very pleasing in colour, rose-lilac, which passes to white, and shaded with a rosy tint, whilst the centre is yellow. Autumn Queen is a slim, early kind; the petals broad, drooping, and deep-yellow, touched with rose. Mme. Dufort is of a crimson-red colour, with tinge of gold to the petals, whilst the centre is of a similar shade. Note may also be made of Mme. Mathilde Cassegrain, which have a large flower, and of nonken-yellow colour, tinged with violet-rose, whilst the centre is yellow, shot with salmon, a soft association of colouring, one melting into the other. Madlle Marguerite Puaige has a crimson flower, with a shading of light-buff, and the central petals are reserved, showing the old colour. M. Pierre Cassegrain has a crimson flower, with the petals tipped

Group of early-flowering Chrysanthemums.

are in many cases fast expanding, and unless where growing in mellow and shady situations a few cans of water or liquid-manure once or twice a week will do the plants a world of good, and increase the size and number of the blooms wonderfully. In all town gardens a collection, larger or smaller, of these charming plants is absolutely indispensable, for with plenty of these and Chrysanthemums there will be no lack of bloom until the winter fairly sets in. An excellent companion to the Asser is the stately Pyrethrum uliginosum, one of the most graceful of all autumn flowers, and which thrives and blooms abundantly in all but the very coolest places. In the greenhouse Fuchsias are fine now, provided they receive abundance of moisture and a moderate amount of shade, and they are also very useful in shady borders and window-boxes. Begonias in pots that have done flowering should be stood out under a sunny wall until the foliage and stems die away, or sharp frost sets in, withholding water by degrees as they go to rest; then bottom them, and keep the tubers or pots cool and dry, yet safe from frost. Get the last batch of "Geranium" cuttings inserted as soon as possible. If wet or cold weather sets in they will do better under glass than outside. Early-struck cuttings of the large-flowered Pelargoniums had better be potted off singly as soon as fairly rooted.

opening, as will be shortly. Potted a number of Begonias. Looked over the forcing Chrysanthemums to take off runners, which the plants are inclined to produce now, and opened the plants out to give free access to air to ripen growth. Sometimes manure-water is given with the view of giving substance to the crowns, but for early forcing the advantage is very doubtful, and if the plants are growing in good substantial material liquid-manure is not required now. I am still putting in cuttings of bedding "Geraniums." Not because I believe in late propagation, but the beds must not be cut hard in early in the season. If I had the space I should like to plant out stock of the principal variety to the reserve garden for the purpose of producing cuttings; but this cannot be done only to a very limited extent. Have discontinued picking of flower-buds from Zonal Pelargoniums intended for winter blooming. They will soon be placed under cover, as shelter from heavy rains will be necessary now. Potted up Arum lilies from open air bed, and lifted Salvia and Eupatoriums from bed where planted to make growth. These plants are much larger, and will throw more bloom than when grown in pots, and with care there will be no check given. The plants are doing better potting in the shade of a lolly wall than they were established. Will be taken indoors before frost comes, as Salvia especially will not bear much frost.

colour, with stripes of rich crimson. Alfred Fleuret is a charming kind, the flowers thin, but very pleasing in colour, rose-lilac, which passes to white, and shaded with a rosy tint, whilst the centre is yellow. Autumn Queen is a slim, early kind; the petals broad, drooping, and deep-yellow, touched with rose. Mme. Dufort is of a crimson-red colour, with tinge of gold to the petals, whilst the centre is of a similar shade. Note may also be made of Mme. Mathilde Cassegrain, which have a large flower, and of nonken-yellow colour, tinged with violet-rose, whilst the centre is yellow, shot with salmon, a soft association of colouring, one melting into the other. Madlle Marguerite Puaige has a crimson flower, with a shading of light-buff, and the central petals are reserved, showing the old colour. M. Pierre Cassegrain has a crimson flower, with the petals tipped

with old gold, and the centre of a similar colour. Four other varieties deserve mention. One is *M. Zephir Lionnet*, of a rosy-purple colour, very pleasing when the twisted petals are reversed, showing an old gold tone. President Leon Say is of a salmon shade, with stripes of red, the reverse of the petals old gold, touched with violet. Two good varieties are *Souvenir de W. Holmes*, so named after the late secretary of the National Chrysanthemum Society, and the colour of the flowers is crimson, touched with buff, the centre yellow. Vice-President Hardy has a bold bloom, the petals broad, but yellow, with stripes of crimson. This selection will form the nucleus of a good group, and others may be added as opportunity occurs. Each year now many first-class novelties are added, forming a class of remarkable interest and beauty. C. T.

TREES & SHRUBS.

4152.—**Planting Clematis.**—If the plants are in pots you may plant them out at almost any season of the year, but if to be lifted, the autumn and spring are the two seasons for the work. Put them in good garden soil, and the best kinds are the following: *C. Jackmani* is very beautiful; it is almost too well known to need description, and its wealth of rich scarlet-purple flowers never seem monotonous. *C. montana* will also succeed in the position mentioned. It is not so well adapted for a small garden as the others, but it will soon cover the house, creating a sheet of pure white in spring, when the flowers are produced in greatest profusion. *C. flammula* will grow quickly and tall, but there is a host of kinds. You will do well to put your trust in *C. Jackmani* and *C. montana*, the latter being the more robust, but the former may be added to give variety.—C. T.

—The best time to plant is November, as the plants are quite hardy, and they become better established when planted before frosts set in too severely. Any large dealer in plants and trees can supply the Clematis. The plants are generally grown in pots; and good strong ones are supplied at about eighteen-pence each. One of the very best is *C. Jackmani*, raised by Mr. Jackman, of Woking, thirty years ago. This variety has rich purplish flowers. Other good sorts are *Deviensis* (blue), *James Bateman* (pale lavender), *Fair Rosamond* (bluish), *Mme. Van Houtte* (pure white).—J. D. E.

—Any nurseryman will supply plants in pots of the varieties named, they being popular kinds. Any time during March or April is a good time to plant Clematis, the roots taking possession at once of the new soil, growth following in the same order, while any good garden soil, with a small portion of partly-decayed manure added, will grow these plants. A compost of loam, peat, and manure will produce better results. If quick growth is important the extra trouble of preparing the soil is time well spent. Abundances of water at the roots and over the foliage before the blooms expand, and during hot and dry weather, will facilitate progress and prevent attacks of mildew, a fungus to which this climber is subject. It is important that the young shoots be secured to the wall as fast as they grow, not only for the sake of appearance, but for the welfare of the plants themselves. The first named commence to open its sweetly-perfumed flowers in May, and scarcely need any pruning. The second is perhaps the most free-flowering of all the Clematis family. This requires close annual pruning, February being the most suitable period. The blossoms are produced on the current year's shoots. The two latter varieties flower from the last season's shoots, therefore need but little pruning. They flower late in the summer as well as early. *Montana* (pure white), *Jackmani* (rich purple), *Sir Garnet Wolseley* (mauve), and *Empress of India* (mauve, with purple bar).—S. P.

—These may be planted either now, in the early autumn, or in the spring, March or April; but perhaps with such a cold aspect it would be better to wait until the latter time. As regards a selection of the varieties, the best way would be to go to a good nursery and suit your own taste now that they are in bloom. Any respectable nurseryman will supply you with plants.—B. C. R.

4513.—**Brown wood ashes.**—Yes, wood ashes of this or any other hard wood form an excellent addition to potting soil. The best way is to fill the surface of the rougher parts for drainage, and of the smoother sides with a two-inch part of the whole may be added to the compost and thoroughly mixed with it.—B. C. R.

4511.—**Clematis Jackmani.**—If you buy a plant in a pot in the spring, and put it in with half a barrow-load of good loam and well-rotted manure, it will make good growth during the summer. In the autumn, when the leaves have died, cut it down to within about 6 inches of the ground and cover the base with fine ashes; the object of cutting down Clematis is to strengthen the plant and make it throw up additional shoots; when as many are produced as you require a little trimming will be sufficient.—A. C. BUTLER.

—There is no better time for planting Clematis Jackmani than the present. It will strengthen the bottom if the plants are cut down at the end of the first season after planting, though many plants are not cut down at all, but simply allowed to grow and get strong in their own way, which they will soon do if the site has been well prepared. Whatever pruning or shortening back is necessary should be done as soon as the buds show signs of moving in spring. In a general way all the pruning required is to dress the plants over by the removal of dead growth, tendrils, &c., or shorten back weak shoots.—E. H.

—This free-flowering variety requires close annual pruning to give it vigour of growth. Early in February every year cut back the whole of the previous year's shoots to within an eye or two of the base from whence the growth commenced. In buying a new plant the chances are that it would be cut down in the manner indicated at the time of purchase, say end of March or early in April, that being a good time to plant any kind of Clematis, for the reason that growth is then active, and the roots quickly take to the new soil. This variety is most accommodating as to position, while a southern exposure is perhaps the best; it will succeed very well on a northern aspect, and certainly capitally against a west wall or screen. Any good garden soil will suffice, provided abundance of water is given the roots during hot weather in summer, with an occasional dose of liquid-manure at the roots, and the foliage vigorously washed with clear water sometimes, always choosing the evening for this. During a summer like the present this Clematis is subject to attacks of mildew if the roots are not maintained in a moist state; this fungus, of course, prevents the blossoms expanding properly. If it is necessary to provide fresh soil, owing to the present being untried, a small quantity of peat, added to some fibry loam and half decayed horse-manure, makes a capital compost. The shoots ought to be fastened to the wall or trellis as they grow.—S. P.

4450.—**Araucaria.**—I have answered several queries respecting this tree in *GARDENING*, and can sympathize with those who wish to keep the "Monkey Puzzle" in good health; but the fault is in planting such a tree, which is never satisfactory, except under certain conditions. One of the finest specimens in England is at Dropmore, but there everything in the Conifer way thrives luxuriantly. There is practically no remedy when the tree is in the condition mentioned by you. Evidently the root is not deep enough, or it has, like in so many gardens, finished its course. Even in such places as Kew, where everything possible is done to promote their welfare, they are in a half dead or dying condition—an eye-sore rather than an attraction. Why they are planted is a mystery. I hope no reader of *GARDENING* will plant the Araucaria unless he is assured beforehand that the position is in every way suitable for it. Moreover, its peculiarly distinct character is completely out of harmony with the majority of things in gardens.—C. T.

4458.—**Striking Ceanothus.**—The varieties of Ceanothus are all evergreen, therefore their leaves do not fall off. The best time to strike cuttings is during the first or second weeks of September. Choose half ripened shoots of the current year not over-strong, cutting them into 6-inch lengths, be careful to cut squarely across below a joint, from here roots are formed, if the cut is made half way between two joints, the stem decays right up to the joint, and the cutting fails to root. Dibble them firmly into sandy soil in a 6-inch pot, or if a quantity are required place a 1-inch layer of sandy soil in a shallow frame, making it quite firm, sprinkling a little sand on the surface to be carried down with the dibber.

on this sand at the bottom of the hole the cutting rests. Roots form quicker in sand than soil. Give a gentle watering to settle the sand and soil about the cuttings firmly, as without the base of each is quite firm they cannot make roots. Plunge the pot in ashes up to the rim in a cold frame, give shade when required if the sun is powerful, and keep the frame close, with the exception of admitting a little air for an hour each day to dissipate condensed moisture. By the following May they ought to be nicely rooted and be ready to plant out where required. It is not necessary to provide rich soil for any kind of Ceanothus; they grow freely in any garden soil, provided abundance of water is given the roots during the summer; too gross a growth is liable to injury during the winter from frost.—S. P.

4509.—**Outtinge of "Geranium," Pansies, &c.**—Cuttings of Zonal Pelargoniums should have been taken in August and rooted in the open ground, but the continuous drought has prevented my plants from producing wood, so that I shall have to pot up the old plants and take most of my cuttings early in the spring. Pansies have suffered even more severely, but with a little wet weather will doubtless shoot out young growth. When this appears take up the old plants and pull them to pieces, using each shoot with a few roots attached as a young plant. These rooted shoots are more certain than cuttings, although the latter may be struck at any time from now up to the commencement of the winter frosts.—A. C. BUTLER.

—For "Ceranims" the beginning of August is the best time, in my opinion, inserting the outtings in the open ground; but they may be got in, in pots or boxes, up to the end of this month (but the sooner the better), placing them in a half-shaded spot in the open until cold or wet weather sets in, then house. Cuttings of Pansies may be struck in a cool-frame, or under a handlight, in July, August, and September, or in March on a gentle hot-bed. Those of Gooseberries and Box may be inserted early next month in the open ground.—B. C. R.

—I have before given advice on this point. Now is the time to take cuttings of Pansies, and the work should not be delayed. Select short, stubby side shoots, which should have, if possible, what is called a heel, as they root much better under these conditions. Make up a little bed for them in a cold frame. Any old light will do, as they merely want protection for a time. But even this treatment is not essential, only there will be far fewer failures than without the light. When the cuttings are put in give a gentle watering through a fine-rose watering-pot. In the spring they may be lifted and planted out in the positions they are to adorn. Remember that Pansies require a deep, cool, moist soil. "Ceranims" may be struck from well-ripened cuttings in the open if the work is done at once, as we may in a week or two's time get an early frost, but the soil at present is warm. It would, perhaps, as the season is getting so late, be better to put the cuttings in pots, inserting them round the side of 5-inch size and placing them in the greenhouse. They will root readily, and ordinary garden soil will suffice. During the winter keep them on the dry side, free from decaying weeds, and before planting out pot them on so as to get good plants for the garden.—C. T.

4507.—**Treatment of Lilies.**—You may plant the Lilies in the autumn, as thousands of bulbs of *L. auratum* are purchased about this time at auction sales, and put out in the garden. You may keep your bulbs in pots until the spring, but it would be better to get rid of them at once. I much prefer Lilies in the open than in pots, and if you have Rhododendron beds, or of American plants, such a spot would suit the Lilies to perfection. They go well with evergreen shrubs, and the rising shoots in spring are protected from late frosts, whilst the flowers of both Lilies gain in contrast with the shrub foliage. *L. lancifolium*, or *L. speciosum* as it is also called, is very pretty when thus associated. Plant carefully in well-prepared soil, and if the position is in a border, see that the steeple is good deep loam. When they have been in this place for a year, apply a top-dressing of manure, but this latter should not be dug in the soil. Lilies do not appreciate it greatly in actual contact with the bulbs.—C. T.

FERNS.

DAVALLIAS.

THIS genus, established just a hundred years ago by Sir James Edward Smith, the first President of the Linnean Society, represents a few beautiful plants, and they are very useful for general decorative purposes, either grown in pots, or when placed in baskets and hung up to form ornament in this way. As a family it has been considerably extended by the addition of many species which other authors class as *Leucostogias*, *Ilumata*, *Acrophorus*, *Odoatosoria*, and some others; but the true *Davallias* only are included here, and they are distinguished by having the *Indusium* attached by its base and sides, and buried in the substance of the frond—a little pitcher-shaped chest enclosing the spores. These plants are all creepers or of sub-erect habit, with mostly firm and shining green fronds; and they are deservedly popular, from the stout rhizomes which are clothed with large and stout chaffy scales, and which give them the appearance of hare's feet. They are popularly known as Hare's-foot Ferns. These plants require to have their fronds pegged down upon the surface of a good turfy peat soil, being careful not to bury them beneath the surface. Indeed, we once saw a collection of these plants entirely destroyed by being potted in this manner, so that we particularly wish to call attention to the fact, for if their rhizomes are buried in the soil it has a very injurious effect upon them. As before remarked, they make handsome plants when grown in hanging-baskets, whilst the cut fronds of many of the kinds are charming when used as the background or framework for a shoulder spray, and for the decoration of ladies' hair for an evening party; but in the latter case small fronds must be chosen, whilst others of larger size are very useful for wreath-making or similar purposes. They require a larger surface space than depth of soil, and their rhizomes should be moderately raised above the surface in a little ridge or mound, and be pegged down to the surface, and by this means remarks my friend "Jane Hudson" will, I hope, endeavour to see her way to growing some of these Ferns well. Some of the very best kinds I here briefly describe—

D. BULLATA.—This is a particularly interesting plant, and one that is easily recognised, for now, at this season of the year, the fronds begin to turn yellow and fall away, until in the autumn they are all fallen, leaving nothing but a mass of bright-red rhizomes, and which are very appropriately named *Squirrel's Legs*; but in the spring time, when the young fronds are unfolding, it is one of the most charming plants that I know. The fronds are some 6 inches to 9 inches long, or more, and they are about 4 inches to 6 inches across. Small fronds of this plant are well suited for personal decoration, or for cutting to mix with cut-flowers, and it makes a fine plant for climbing over and up any place; but it requires to be so set that it does not remain in sight during the winter season, because at this time it is devoid of all its fronds, nothing being left but the bare rhizome during the winter, so when the plant is dormant it should be kept in a cooler house, and the plant be kept moderately moist. Much damage I have seen come to this species through being kept too hot and too dry.

D. CANARIENSIS is the typical plant known as the Hare's-foot Fern, and it is a plant that is found in the South of Europe, in Madeira, and the Canary Islands, so that it naturally comes to be a cool greenhouse plant; but I have never seen this *Davallia* so fine as when growing in a nice warm greenhouse; it has fronds some 12 inches or 18 inches broad and much divided, and of a rich deep green.

D. DISSECTA (No. 1) of the set sent by "J. H.".—It is a plant that resembles "Cacode" very much, but it is stronger in its growth, and it has stouter rhizomes, and these are

coated with large pale-brown chaffy scales; it, moreover, is an evergreen plant and retains its fronds in all their verdure through the winter months, requiring the heat of the stove.

D. FIDUCIARIA (here figured) and its variety *plumosa* are amongst the most beautiful of any known Ferns; but coming from the Fiji Islands, of course, they are stove plants. Your No. 4 is either the species or its variety *plumosa*; the rhizomes are small, the fronds large and broad, finely cut and divided, and rich deep-green in colour.

D. FALLIDA, better known in gardens by the name of *D. Mooreana*, is a thoroughly distinct plant; the rhizomes are somewhat underground, and it has large and spreading fronds which are very distinct and very elegant. I have found that it stands well when cut and put with out flowers. This is No. 3 of "Jane Hudson's" specimens. I cannot make out No. 2; it is too small and the fronds are not fertile, neither does she give me a bit of the rhizome to look at.

J. J.

4180.—Plants for winter.—Every one, I think, is of the same opinion as yourself. We do not want winter to destroy the present beautiful aspect of the garden but unfortunately we cannot hinder the arrival of frosts. Enjoy the flowers whilst there is time. Your question

Davallia filicoides.

is somewhat foolish. Of course you cannot keep the garden as gay in winter as in summer, and those who love flowers seek the greenhouse or the conservatory in the winter months to enjoy plants. All you can do is to hope that frosts will keep off until late in the year, and get in some time in September plenty of bulbs—White Aconites, Snowdrops, Crocuses, and other early flowers. If you have such things as the *Polygonum cuspidatum* in the garden, leave the stems, as their polished nut-brown colour is very pleasing in the "dark" months of the year. The fragrant *Coltsfoot* will scent the garden in December, the *Hellebore* flower if the weather is at all kind, and the *Winter Cherry* (*Physalis Alkekengi*) will make a gay patch of colour with its crimson-coloured calyxes that hang like little Chinese lanterns on the leafless shoots. The best *Hellebore* is major; but one does not often get the plants in bloom in December. You can also plant the form *atitollis* which blooms earlier. To keep the flowers pure in colour, put over each clump a bauble of light, to protect them from rains and frosts.—C. T.

4518.—Medlar and Rose.—The first of these is a fast grower during the first ten or twelve years, after this it seems to grow less quickly, although in reality it is not so. The rate of growth being spread over a more numerous body of branches. The thick lignified

you mention from a cesspool is far too strong for Rosee, whether established or not, unless it be freely diluted. Strong doses of manure do no good, and you cannot possibly apply enough to reach more than a few of their roots; and this is oftentimes fatal. Reduce the sewage, and then apply liberally enough to reach the bulk of the Rose roots. Your fear of over-manuring is useful, and not enough practised by the majority of amateurs.—P. U.

—The Medlar is not a quick-growing tree, but it is most picturesque, and when small is very charming on the outskirts of a lawn, especially in early summer, as then the branches are studded with the pure white flowers. Certainly do not use the offensive stuff you write about. You will kill your Roses, and such material, if used at all, which is not necessary, must be greatly diluted. I know a splendid garden of Roses where comparatively little manuring is done. The soil is excellent, and suitable top-dressings are given in spring; but the beds are not soaked with nasty liquids that make the garden positively noxious. Fancy soaking the beds with such muck! The fragrance of the flowers is destroyed, and no one who respects his nose could go within yards of the plants. This is not gardening.—C. T.

—The Medlar is the slowest grower of all fruit-trees, and never attains the proportions of a large tree. It only passes under the designation of a tree by courtesy; it certainly has no rightful claim to it. There is no doubt but that the thick liquid from your cesspool is too strong to be given to any plant or tree. I should say for Roses it wants diluting with six times its bulk. In that state it may be given once a week in dry weather all the summer.—J. C. C.

ORCHIDS.

BARKERIAS.

I AM asked by "John Foden" to say a few words about these plants, which he calls *Epidendrums*: Now I am somewhat old-fashioned, and I like to keep to the old name of a genus until I can see some cause for altering, and in the present instance I think the genus *Epidendrum* is cumbersome enough. "J. F." appears to have been growing his plant of *B. Skinneri* quite right and well, and I have no doubt if he still continues to treat it in a rational manner that he will be rewarded with a fine display of bloom about the middle of November, for I do not think that there will be any plants this season which will be slow in sending up their spikes of bloom; but in some seasons I have seen that species in flower at the end of the month of March; but, of course, as these flowers last for several weeks in full beauty when treated properly, such a plant may have opened in the early part of February. To treat these plants properly they must be grown in a cool-house, but they should not be subjected to the same conditions as the *Odontoglossums*, for these *Orchids* like the shade, but *Barkerias*, on the contrary, enjoy bright sunshine, and they like to be kept always during the growing season in a thoroughly wet condition. They are plants too that like to have an abundance of air by both day and night, yet still the atmosphere must always be kept properly charged with moisture, for these plants, although they make thick and fleshy roots, they yet cannot be bound best upon a bare block of wood. Consequently, a tub of water or some such accommodation should always be kept handy, so that they be soaked down and dipped conveniently at any minute in the day, and hung up again directly to drain, and this is the system to grow these plants well, and to continue them on in a healthy condition for years. Do not upon any account experiment with pot culture, for under this routine you are sure to have a miserable failure, for the plants get small by degrees and miserably less. The following are the best of the species and varieties which I have grown myself, and seen others grow, and all are exceedingly beautiful, well deserving the careful attention of every grower of *Orchids*.

B. ELEGANS.—This plant, although found first by the collector, Ross, in 1837, it was nearly twenty years afterwards before it became common in gardens, and even at the present time it is not so common as it was in Mr. Sander's vast

emporium, where almost any showy species of Orchid can be found, it is rare in this country. The stems are slender, about a foot long; the leaves are deciduous, falling away during the resting season, as they all do, and during this time they require to be kept cool, and a great deal drier, but they will require to be dipped about three times in the course of the week to keep the stems from shriveling. The flowers are borne in a somewhat loose raceme, and measure nearly 2 inches across, the sepals end

Lilac Starwort (*Aster elegans*).

petals spreading, white suffaced with rosy-lilac, the large lip being white, with a large blotch of rich and bright rosy-orange near the point. This beautiful plant is the original upon which the genus was founded; but there is another plant which was introduced by Mr. Sander, of St. Albans, a few years ago, and called

B. BARKERIOLA, but it is very nearly allied to it, and probably only a mountain form of the same plant.

B. CYCLOTELLA.—This is another truly beautiful plant. The flowers are as broad as *B. elegans*, and are wholly of a deep-magenta, with a white centre to the lip.

B. LINDLEYANA is a free growing plant, having bright rosy-purple flowers, and a white disc. *Lindleyana Centensis* is a variety with flowers of a much deeper colour. It is also a very free-flowering sort, but the species is very variable in colour.

B. SKINNERI—It is nearly sixty years ago since this plant was first found by the gentleman whose name it bears, and it is one of the most beautiful of winter-flowering Orchids, usually blooming in the first months of the year, the flowers being deep purplish-rose colour, with some orange petals on the disc.

B. SPECTABILIS—It is just turned fifty years ago since this beautiful kind first flowered in this country. In growth it is similar to the other species, and it produces flowers about 3 inches or more across, and these are rosy-lilac, the lip nearly white at the base, dotted with bright-red. It blooms during the summer months, and is a very desirable plant.

MATT. BRAMBLE.

4478.—*Agapanthus umbellatus albus*.

—I see no reason whatever why this plant should not submit to moderately early forcing if they are properly prepared, by which I mean given a good rest before introduced into a warm house. The end of January is probably as early as it is safe to begin forcing, and no doubt it will respond to fire heat sooner the second year than the first, as it would die down earlier and so secure a longer rest and be ready for forcing in a corresponding time. Your experience proves that both the blue and white variety require the same treatment, and that it is wrong to keep the plants altogether without water during the winter. If your plant wants repotting let it be done as soon as the flowers fade. It will then be well established in the soil when the time comes to force it again.—J. C. C.

4479.—**Gas-lime and wireworms**.—You may safely put fifteen or sixteen cart-loads of gas-lime on two acres of ground. I should advise it being applied very shortly now; spread and let it lie on the ground for three or four weeks, then work it in, and do not sow or plant anything before next March.—E. C. R.

OUTDOOR PLANTS.

MICHAELMAS DAISIES (ASTERS).

This genus, as is well known, is one of the most puzzling amongst hardy flowers to the botanist as well as the gardener. Hardly two collections are named alike, and something like uniformity is very desirable, seeing that new seedlings are being raised annually by our growers, and there is now little doubt that

Aster hybridus as freely as *Aquilegiae*. When the greater part of our autumn flowers begin to show the woe and yellow leaf, Michaelmas Daisies are looking their very best, and even long after the early frosts have blackened the Japanese Windflowers and the Dahlias, Asters stand out almost alone bright and cheerful, with their varied starry flowers and graceful arching stems. Beginning to bloom as they do early in July they carry us well into November. It is very remarkable that comparatively little notice is taken of the rapid advance Asters are making in size and colour of flower. In many old gardens you still see the very worst and poorest of the *A. Novi-Belgi* forms, with which our later acquisitions are not to be compared. Planted in groups amongst Rhododendrons and other dwarf shrubs is no doubt the way to see Asters at their best. Under such conditions they require no stakes, and little care; they take up no space that is otherwise wanted, and all through the autumn and early winter they are very refreshing. What could be better than masses of such species as *A. cordifolius*, *Shortii*, *Drummondii*, and *agittifolius* in our woodlands, or even amongst our choice shrubs. While the stronger varieties of *Novi-Belgi*, such as *Robert Parker*, *Archerfield*, *Harpur Crewe*, *Apollo*, *formosissimus*, *Purity*, and *floribundus*, might be grouped with effect amongst our Rhododendrons and coarser growing shrubs? Their habits are so varied and their flowers so beautiful and changing that there is hardly a limit to what may be done in the autumn garden with Michaelmas Daisies, while the delicately elegant branches of the varieties of *A. cordifolius* *Photograph*, *Diana*, and *elegans* remind one more of a clond than a bunch of Daisies. Amongst the Himalayan species two stand out prominently, the one an early flowerer (*A. diplostephioides*) and the other late (*A. Thomsoni*) (see page 399). This latter is one of the most distinct, and, to me, most beautiful and useful of the Himalayan Asters in cultivation. It rarely exceeds a couple of feet in height, is of a neat compact habit, the large pale-lilac flowers being produced in great abundance on strong plants. The stems are very leafy, the leaves broad and distinctly toothed, and of a pale green. It begins flowering early in August, and continues until October. It is one of the few Asters that will not stand division. The best way to increase it is from seeds or cuttings of the young shoots in spring. *A. diplostephioides*, re-introduced by Kew last year, is a giant amongst Asters. The flowers are solitary on long straggling stems, 4 inches in diameter, rich bright lilac purple, with a golden disc. *A. Schreyeri* is a dwarf trailing species more suitable for the rockery, and readily increased by stolons. Of the European species, *Amellus* and

acris are by far the most useful in the garden. This latter species is a most variable *Aster*. *A. Amellus* is also variable, the varieties in the garden being called *major*, *bessera*, and *smellioides*; but I confess to seeing little more varietal difference than might be readily got from a packet of seed. By this we may, *Amellus* is a fine *Aster*, and so bright and neat that we can hardly have too much of it. The great centre of the Michaelmas Daisies is North America, and to this group belong most of those grown in the garden. Perhaps no less than two-thirds of our cultivated Asters may be traced to *Novi-Belgi* pure and simple, or to hybrids between that species and *A. laevis*, another remarkably beautiful and extremely graceful species, of which there are two or three distinct varieties. To *Novi-Belgi* belong the named varieties known as *Robert Parker*, *Andromeda*, *Harpur-Crewe*, *Cellops*, *densus*, *Flora*, &c.; indeed there are no less than between forty and fifty distinct garden varieties, among which are some of our loveliest autumn flowers. *A. Nova-Anglia*, with its robust habit and large rose and purple flowers, stands head and shoulders above all the other species, a grand border plant and a free bloomer. *A. patens*, *patinus*, *polyphyllus*, *salicifolius*, *turbinellus*, *paniculatus*, *tataricus*, *umbellatus*, *multiflorus*, &c., are all worth a place in the garden, while amongst the dwarf kinds, *A. scaberrimus*, *ericoides*, *Lindleyanus*, *versicolor*, *vimineus*, *spectabilis*, *corymbosus*, *diffusus* var. *horizontalis*, *levigatus*, *nanus*, &c., stand out prominently. There is plenty of scope for selection, and so they are all easily grown in any good garden soil, they will be found most desirable additions to the autumn flower garden. All the species may be raised from seed; the majority are readily divided in autumn or spring, and most of them may be increased from cuttings taken off as growth begins in spring. K.

4524.—Transplanting White Rockets.

—The proper thing to do is to plant them out in the positions they are to be beautiful, and this should be done when the weather is not too dry, but before frosts occur. Rockets require frequent transplanting, and plants two years old should be divided. The majority of hardy plants do not like disturbance at the root, and the Rockets are an exception to the rule. The soil for them should be fairly moist, well prepared, and if this treatment cannot be given, they are very unsatisfactory.—O. T.

—The single Rocket is so hardy that you may transplant them at any time. A few of the plants set out now in an open place will do better than those that are left crowded, and will probably give you all the flowers you want. Seedling Rockets are not very choice subjects, and as you do not appear to know what they are, I advise you not to burden yourself with a great number of plants. It will be better to devote the space to something else.—J. C. C.

—I find the best time to transplant the Double White Rocket is immediately after flowering, breaking the roots up into moderate sized pieces, and setting them out 15 inches to 18 inches apart; but plants raised from seeds would be stouter, and not so valuable, and if not too crowded might be thinned out now—better now than wait till spring.—E. H.

4505.—**Manuring ground**.—The only artificial manure (if it can be so termed) that should be applied in the autumn is lime, which is almost equally beneficial, applied in moderation, to either light or heavy, or poor or rich land. Spread it thinly over the surface, let it lie two or three weeks, and then dig it in. Stable or farmyard-manure is, as a rule, best dug or trenched into the ground in the autumn, while nearly all the numerous artificials, simple and compound, should be applied in the spring or summer, just as the new growth is commencing, and in some cases again afterwards a short time before the plant has to make any special effort. For general outdoor purposes I know of nothing to equal Thomeon's Viper and plant-manure, though for certain crops the silicate is also excellent.—E. O. R.

—Artificial manures are best used after the crops are planted, or at the time of planting. If dug in during the winter a large percentage will be washed out before the plants could use them.—E. H.

4501.—**Nitrate of soda**.—The soda may be applied in the state in which you receive it, and from early spring until late in summer. It is, however, best to apply it in showery weather.

If you want to permanently benefit your lawn, you had better lay out your money on rotten manure or good earth, and give it a dressing early in the month of November. Such an application will do ten times more good than any of the forcing manures like that to which you refer, as they are quickly exhausted. I dealt with a cricket-ground about this time last year in the way I suggest where the sward had nearly disappeared, owing to the constant play, and it quite recovered by the spring.—J. C. C.

— The proper time to apply this excellent stimulant is during the spring or early summer, just before the young growth commences, or, in the case of a lawn, at any time up to the middle or end of August; it is too late now. The right way to apply it is either in the solid form, just before rain, crushing it finely first, and then sprinkling it evenly over the ground at the rate of 2 lb. or 3 lb. per rod; in dry weather it should be dissolved in water at the rate of 1 oz. to each gallon, and the lawn be thoroughly soaked with the liquid. It takes some little time to dissolve perfectly in cold water.—B. C. R.

— The easiest way of applying nitrate of soda is to sprinkle it evenly over the lawn in showery weather, or just before rain is expected. The present is a good season to use, as after the scorching summer the turf needs support.—E. H.

4520.—**Hiding a block paling**—There are many plants suitable for the purpose, and we should try a Gloire de Dijon Rose which would look remarkably well in such a position. The heavy, fragrant flowers would be in fine contrast. Clematis Jackman is another good climber for the purpose, or C. montana, which produces a wealth of white flowers in spring. Plant also Jasminum nudiflorum, which is studded with yellow flowers in the winter and spring months. A few Ivies, good kinds, such as Emerald Gem, Kerria japonica fl. pl., the Jew's Mallow (which has rich-orange double flowers), Honoyonokles, Pyracantha, or Fiery Thorn, and the Wistaria. There is no want of subjects, and you may make a selection from the above named. I have not mentioned Virginian Creepers, as they are planted every where. One gets tired of them, even of the useful Ampelopsis Veitchii. The position is too shady for the Rose. Try the Ivies, and I have seen the yellow-flowered Clematis succeed well in such a spot. The soil must be well prepared, or they will grow in poor stuff, riddled with the roots of the trees, and keep the soil moist for a time. We may have plenty of dry weather yet.—C. T.

— Why not paint the paling with an enviable green colour first, and plant overgreen Privet, Irish Ivy, or common Laurel, against it? The latter would perhaps grow better under the trees if the soil is at all heavy. The chief point in planting either of these subjects is to properly prepare the soil first by digging it at least 2 feet deep and adding plenty of manure if the soil is poor. Should the first be dry after planting give abundance of water to the roots of the newly planted shrubs, as under the trees they would suffer otherwise. It is useless to plant any of the usual quick growing climbing plants, like Convolvulus for instance; the position is not at all suitable.—S. P.

— There is nothing better than Ivy. Strain a few wires along, as Ivy will not cling well to black pallings.—E. H.

— Irish Ivy and Virginian Creeper would soon cover up the ugliness. Neither of these seem to object to being ever shadowed.—A. G. BURLING.

4471.—**Wood ashes.**—Why not make them yourself? It is only necessary to make a fire, and when well started, put on a lot of any rough wood, let it get well alight, and then partly cover it with weeds, rough bits of turf, or garden refuse of almost any kind, just to check too rapid combustion. In a garden of any size a fire of this kind ought to be made frequently, or even kept going almost constantly; for one thing it is by far the best way of getting rid of all the rubbish, and for another the products are invaluable not only for potting purposes, but as a top-dressing for many vegetable crops in seed-beds, &c. Such burnt material is equal in value to any artificial manure, especially for Turnips, Carrots, Onions, Potatoes, and other root crops.—B. C. R.

ROSES.

4510.—**Roses for button-holts.**—Duo de Rohan and Prince Camille de Rohan are undoubtedly the two best growers amongst those of a dark velvety colour, but the forms of the flower-huds are hardly so suitable for your purpose as some others. Regarded in the latter light Emperor and Emprise are the best, but they are poor doers, being much subject to mildew. On the whole, I think the two first named and General Jacqueminot and Chariss Lefehvre will suit you admirably as dwarf plants. You must plant them in good soil, and only prune moderately.—J. C. C.

— I would choose the following four varieties as being the best dark velvety Roses for coat-flowers under glass: Prince O. de Rohan, General Jacqueminot, W. F. Bennett, and Fisher Holmes.—P. U.

4504.—**Roses from cuttings.**—Cuttings of all kinds may be rooted in bottles of water. Small bottles are best that will hold only one or two cuttings, which should be made of firm wood, and taken off, if convenient, with a bit of older wood. The bottles should be hung in a light position. They may be hung against a wall in the open air if cuttings are put in now. When water evaporates the bottles must be filled up.—E. H.

— I do not see why you should wish to root Roses in bottles of water, unless as an experiment. However, they may be rooted in this way. Choose young growth about half ripened, and use a glass bottle with clear rain water. Place a few pieces of charcoal in the water to prevent putrefaction, or the young roots will commence to rot off just as you were about to pot them up. An ordinary living room or greenhouse will do very well to keep the bottles in; but Roses are rooted much more safely and satisfactorily in a sandy soil compost.—P. U.

— Although Roses strike fairly well in bottles of water in heat it is a much more certain method of propagating them in a cold frame, or even out-of-doors entirely they strike readily. The point is to have cuttings of the right kind; those that are soft and unripe are not suitable. Shoots of the current season's growth in a half-ripened state, cut into 6 inch

lengths, strike root easily if not square below a joint, and inserted firmly in sandy soil. It is most important, however, that the soil at the base be made quite firm; if not, roots cannot form. If a frame is to be used no time should be lost in putting in the cuttings. A layer of soil, 4 inches thick, on a bed of coal-ashes, made firm, affords a sufficient rooting space. Give a good watering afterwards, to settle the soil about the cuttings. Keep the light bottles except for an hour occasionally; it should be

tilted a little to dissipate condensed moisture. If the sun is powerful shade the cuttings from bright sun to prevent their flagging. If the convenience of a cold-frame does not exist a good strike is possible out-of-doors. Choose a sheltered border; chop out a trench, 4 inches deep; scatter some sand along the bottom of the trench; make the cuttings 8 inches long, and plant them firmly in the trench 3 inches apart; tread the soil firmly about them, and mulch the surface between the rows with leaves, coal-ashes, or Cocoa-nut-fibre refuse to prevent the frost lifting the cuttings out of the ground. The end of September is early enough for this plan.—S. P.

4516.—**Roses in beds.**—"Inquirer" should not touch his plants with the knife until early next spring. A full description of pruning, more so than could be incorporated in the reply to a single question, will appear in these pages in due season. The best plan will be for "Inquirer" to wait until then, carefully persevere it, and pay great attention as to whether his sorts are suitable for pegging down or not. In the meantime he may mulch them with stable manure as soon as winter approaches.—P. U.

— Much depends upon what the Roses are. Hybrid Perpetuale may be cut back at the end of April to within 9 inches of the ground, all ugly sprigs and very old wood being removed. Teas should not be cut back in the same way; but the long straggling shoots may be shortened in the autumn, and unsightly branches removed.—A. G. BURLING.

4525.—**Rose Gloire Lyonnaise.**—By no means out the shoots back, but leave them to peg down next year in the place of those pegged down this year. I have treated it so for six years, and now the plants have shoots 6 feet long for another year. It never fails to send up an abundance of them, and they sometimes flower at their tips. It is not a great autumn-blooming Rose like the true Teas are.—A. H.

— Your question as to whether you are letting your plant make too much growth depends on the space available. If there are uncovered spaces after you have allowed a width of 9 inches for each branch you may peg the new-made shoots down at once. If there is not so much room available, and there are no signs of flowers upon the old wood, you may cut out the latter at once and peg the other down in its place. Under any circumstances the old wood should be cut out in winter when there are young shoots to take its place, always assuming that there is a sufficient number of the latter to cover the surface. Although Gloire Lyonnaise is a beautiful Rose, I think it is more suitable for covering a pillar than for the purpose you are using it. Should you be writing again would you be good enough to say if you find the flowers have a pendent habit when the growth is pegged down, as I am interested in this form of Rose-growing?—J. C. C.

— "Micawber" is treating this Rose correctly. By all means let him encourage the long upright shoots breaking out from the base. These must be pegged down next year in place of those which were pegged down and bloomed this summer. It is best to cut away the old wood which has already flowered, and so throw more strength into the new shoots. The old wood would have to be removed next spring, if not done now, and it is useless to allow it to absorb so much of the plant's energies. Besides, you can manure and work the ground during this autumn, if such wood is cut away now.—P. U.

4520.—**Treatment of Roses.**—From your description you are evidently treating the plants very well, and I heartily wish you the success you deserve next spring. Keep the plants rather dry at the roots for a few weeks, and admit as much light and air as you possibly can. This will conduce to better ripening of their wood. No artificial heat at present. Prune early in January. You ask in what manner, and do not give any names of the varieties. Presuming that they are all strong climbers, prune very slightly, merely cutting away immature tips to long growths, and any weakly or extra tips that may exist.—P. U.

OUR READERS' ILLUSTRATIONS: ASLEY THOMPSON. Engraved for GARDENING ILLUSTRATED from a photograph sent by Miss E. Wolley Dod, Edge Hall, Malpas, Cheshire. (See p. 395.)

lengths, strike root easily if not square below a joint, and inserted firmly in sandy soil. It is most important, however, that the soil at the base be made quite firm; if not, roots cannot form. If a frame is to be used no time should be lost in putting in the cuttings. A layer of soil, 4 inches thick, on a bed of coal-ashes, made firm, affords a sufficient rooting space. Give a good watering afterwards, to settle the soil about the cuttings. Keep the light bottles except for an hour occasionally; it should be

next spring. Keep the plants rather dry at the roots for a few weeks, and admit as much light and air as you possibly can. This will conduce to better ripening of their wood. No artificial heat at present. Prune early in January. You ask in what manner, and do not give any names of the varieties. Presuming that they are all strong climbers, prune very slightly, merely cutting away immature tips to long growths, and any weakly or extra tips that may exist.—P. U.

4514.—**Unhealthy Roses.**—Your Roses are suffering from the most dreaded of all pests—mildew. The cause of this fungoid disease is sudden changes in the temperature or drought at the roots; or perhaps this season it is both combined. The prevention is difficult in the open ground, where we are almost entirely at the mercy of the elements; but under glass it is not so difficult. Frequent syringing with a weak solution of any insecticide containing a little paraffin, at the rate of a tablespoonful to a gallon of the solution, also a little flowers of sulphur, will kill it; but the whole mixture must be kept well stirred at the time of application. If practicable, remove the cause as much as possible, or no permanent benefit can accrue. Mildew is generally more or less prevalent in the autumn, when cold nights and mornings are followed by hot and bright days.

—P. U.

—Your Roses are afflicted with mildew, canned, I have no doubt, through the want of water at the roots. A cheap and very effectual remedy for it is dust from a public highway. If the bushes are liberally sprinkled with it the mildew will disappear, at least for a time, but a good root watering is also necessary. You must understand that I do not claim any special value for road dust in this direction, further than it possesses the same power as any other material that is made up of minute particles, by drying up the fungoid growth of which mildew is composed. Perfectly dry dusty peat, if shaken on the leaves, has the same effect. It is well known that sulphur will destroy mildew, but that is a remedy that is more costly than road dust when there are many plants to be dealt with.—J. C. C.

—The plants are attacked by mildew, which is far too common among Roses this season, owing, of course, to the excessively dry weather. If they had been kept well watered with liquid manure at the roots, and frequently syringed overhead, this would probably not have occurred, and you may have some trouble in subduing it now. The foliage may be thickly sprinkled with sulphur, but a better remedy still is the Mildewmors advertised in GARDENING, which will soon get rid of it.—B. C. R.

4530.—**Management of pot-Roses.**—You ought to have put a thick shade on the glass over your Roses; indeed, the whole of the roof should have been shaded in such weather as we have had this year. It was quite right to place the plants out-of-doors, but as they did not improve I am afraid the roots did not get all the water they wanted. If the plants want repotting you may do it now, using for a compost good turfy loam and a little sand mixed with it. When repotted place them in the house again.—J. C. C.

—Here is a short outline of the routine for a cool-house such as you describe. Procure your plants as soon as possible, if from the open ground. Pot them into the following compost. Loam, one-third; leaf-soil and manure, one-third; the remainder being made up of any old and well-decayed refuse from a rubbish-heap. Drain the pots well, and make the soil firm around the roots. Now stand them on the north side of a wall or hedge; or, better still, half plunge them in a cool pit. By January they may be pruned, bearing in mind that different classes and varieties need pruning in different manners, and which have frequently been described in these pages. Let them come on as steadily as possible, and when the temperature rises to the heights you mention, or even before that, give your glass a slight shading with some wash. You must keep them clear from insects and also maintain a fairly even temperature; say 40 degs. to 50 degs. during the winter, and gradually rising to 60 degs. and 70 degs. through the summer months. While in growth plenty of water must be afforded them, and as the roots permeate the soil, a few applications of weak liquid manure will be very beneficial. By the end of August it is well to rest the plants somewhat, and this can be secured by withholding water and allowing more air, or else by placing the plants in the open air; I prefer the latter plan.—P. U.

4430.—**Fashion flower in fruit.**—Such a crop of fruit is not at all uncommon in a warm dry season. The fruits are useless as food, and the only thing I suggest is to let them get quite ripe and sell them, which some of the wholesale seed merchants might give a moderate price for.—B. C. R.

FRUIT.

SOME GOOD AUTUMN PEARS.

MANY excellent kinds of Pears ripen during the autumn, and it is difficult to make a small selection. Marie Louise (Fig. 1), an admirable kind either for standards or on walls, is too well known to need a word either of description or recommendation. I may say, however, that its season may be greatly prolonged by not picking all the fruit at once and the same time, but a portion only at intervals of a week or ten days.

Fig. 1.—Pear "Marie Louise."

That first gathered will ripen proportionally earlier than the last. Duohesso d'Angonlomo (Fig. 2), one of the largest of Pears, is handsome both in shape and appearance. In warm seasons the flesh is buttery and melting, but frequently it is cross-grained and gritty. It is a noble exhibition Pear, and to ensure its always being good it should be grown on a south or west wall. It is a free bearer in any soil and aspect. Red Doyonné is a well-known little Pear that is always good. I find it succeed admirably grown in the form of bushes, well ploched in, and at the same time fed liberally with manure or manure-water. The pinching checks the growth and makes it fruitful, whilst the manuring increases the size and quality of the fruit. Louise Bonne of Jersey is a Pear well known to most fruit-growers, but amateurs and cottagers do not grow it nearly so extensively as they should do. It is one of the surest of fruiters, either as a standard or on walls, and in quality is all that can be desired, and in a good fruit-room it will keep a month in usable condition. Durondean is one of the most beautiful of all Pears, the skin being a shining russet, streaked with deep red on the side next the sun, whilst the shaded side is, when fully ripe, a pale yellow; the flesh is most delicious, and the tree is an abundant bearer. It is worthy of a wall and the most liberal culture. Calabasse Tougard is also a large, handsome-looking Pear of excellent quality; it is one of the few kinds that ripen best on the trees, but it requires to be used as soon as it is gathered, for it soon rots deceptively at the core; if gathered before it is ripe it rots before it becomes in any way usable, except for stewing. H.

4506.—**Planting Strawberries.**—Make your bed and put out the plants at once, without the loss of a day. Had they been got in in July, just before the rain, you would have had double or treble the crop next summer that any plants set out now are likely to produce. Still, if extra strong runners, with a ball of earth to each, or, better still, plants established in small pots, can be had and planted at once, a fair crop of fine fruits should result next season. A good distance for most varieties, in ordinary soil, is 18 inches apart, with a distance of 2 feet between the rows. As regards the best kinds, British Queen is the finest flavoured of all, and if it can be grown should certainly be included, but it does not thrive everywhere. Falling this, Dr. Hogg is an excellent substitute, and for the two others President and Keen's Seedling will be about the best.—B. C. R.

—The best time to put out Strawberry-plant is early in August. The object of getting them out as soon as possible after the layers are rooted is to have them established and grown into good plants before the winter, so that they

will be strong enough to bear a crop of fruit the following season. Light gravelly soil does not suit the Strawberry, but I have grown on such soils splendid crops every year by treating the Strawberry as an annual. The young plants set out this year in August would bear a crop the following season. New runners would be layered in small pots for a new bed, and the old plants then were destroyed. The ground is trenched and manured well, the plants being set out 2 feet apart. The best three sorts are Keen's Seedling, President, and British Queen.—J. D. E.

—No time should be lost in making a new plantation of Strawberries. If deferred much later the chances of a crop of fruit is very much diminished, whereas if stout plants are put out during the current month a fair quantity of fruit is assured. The best varieties to grow are Vicomtesse Hericart du Thury, Sir Joseph Paxton, and Waterloo. Those ripen in the order named, are all good bearers, and of good quality also. What the first-named loses in size of its fruit is made up in quantity, being a most prolific bearing sort. The land should be deeply dug, or, what is better, trenched 18 inches deep, and should also be well manured. The rows ought not to be less than 2 feet apart, and if 2 feet 6 inches they would be all the better, especially where much foliage is made. The plants will succeed very well 2 feet from each other, in some districts but 16 inches is given; but this is where but a thin crop of foliage is obtained. The soil varies very much in different parts, having a direct influence on the foliage crop, that it is necessary to look around and see what are the state of existing crops in this respect; but the distance named between the rows is sufficient for all purposes.—S. P.

—If very early Strawberries, combined with size, are required, plant Noble. For succession plant Sir J. Paxton and President, and for late use Elton Pine. Plant now, the sooner the better if the ground is in proper condition. Plant 2 feet apart each way.—E. H.

4500.—**Vines in a cool-house.**—Vines may be grown in a cool-house, but if there are facilities for making a border it will be better to plant them out. I have seen Vines carried on for a number of years in large pots and tubs with the aid of artificial manures. And for a small house where there is no convenience for planting out, a Vine in a pot of the largest size will last a number of years; but I think the chief value of pot-Vines consists in their adaptability for early forcing, and so saving the permanent Vines.—E. H.

—No; the Vines will grow far better, as well as require less care and labour in watering, &c., if planted out in a well drained border of good loamy soil than in pots. At any rate, for a few years, or unless they have to cover a considerable space, it is not, however necessary to afford two or three Vines so large and wide a border as is usually supposed, and a border 3 feet or 4 feet in width, and 2½ feet in depth, including drainage, will afford quite enough growth for a small house, and with the aid of some liquid and artificial manures, judiciously applied, they will produce a considerable number of fine bunches annually. To grow a pot-Vine properly requires no inconsiderable amount of skill. B. C. R.

—No, it is not best to grow Vines in pots in a cool-house on account of the labour they give in watering, and also because when the roots have the run of a good border they are more productive, giving a greater number of branches and larger berries. On the other hand, Vines grown in pots will ripen their fruit a fortnight earlier because they start into growth sooner in the spring, owing to the warm air of the house acting on the pot and imparting warmth to the roots. If you use pots 20 inches in diameter, and take moderate crops, 600 set of Vines will last three years.—J. C. C.

4502.—**Packing Peaches.**—To send Peaches safely by post they must be packed well, as things are usually more knocked about in the parcel post than when sent by rail; still I have sent small parcels of Peaches by post quite well. In the first place, strong tin or wood boxes must be used, and the fruit must be packed tightly, so that under no amount of jolting or knocking about will they shift. I should not send more than one dozen in a box, and these should be packed in one layer; therefore the box should be made to fit the Peaches, allowing for a fair amount of packing. A box 4 inches deep

luscid will carry large sized Peaches. The best packing material is paper shavings, but dry clean moss, well beaten with a stick to make it soft and elastic, will do. Place a layer of the packing material to the bottom of the box, and spread over this half a sheet of cotton wadding; then wrap each fruit up carefully in tissue paper, and run a strip of cotton wadding round each fruit to take off the pressure where the fruits meet. This is better than wrapping each fruit in wadding, because the strip may be doubled, and will in consequence offer a larger buffer to the pressure. Turn the remainder of the sheet of wadding placed in the bottom over the top of the fruit, and fill in with paper shavings or Moss. Make the box quite full, place on the lid, tie down with strong string (never use nails). The lids of Peach boxes usually have strips of wood nailed on the under side at each end, so that under any circumstances the lids cannot move when tied down. The fruit should not be dead ripe when packed.—E. H.

In the first place, the fruit should be gathered before it is fully ripe; if left on the trees until quite soft it is next to impossible to pack them without bruising. Instead of squeezing the fruit on the top to test their stage of ripeness grasp the fruit with the hand, giving it a steady pull. If it leaves the stalk fairly easy it is ready for gathering. Wrap each fruit in soft tissue paper two or three folds thick. Then prepare a strong tin or wood box by lining it with freshly gathered Moss, perfectly dry and well beaten to render it soft and springy. The box should not be more than an inch deeper than the fruit, allowing a layer of Moss under and over the fruit. Carefully pack the Moss between the fruits so that they do not touch each other, nor must they touch the side of the box, but be thoroughly surrounded with Moss. Fill the box tightly with the Moss, so that the Peaches cannot move; tie the lid securely over, but do not nail it beyond just a tack or two to keep it in place. Where Moss is not available Cotton wadding or wood wool will answer very well. Nothing is better, however, than the Moss properly prepared.—S. P.

I frequently send both Peaches and Nectarines by post, and they carry admirably if they are packed firmly in light shallow wooden boxes, and one layer of Peaches in each. Wrap each fruit up separately in tissue paper and pack them rather firmly in the lightest wood shavings. This material I like better than paper shavings or cotton wadding. They must be packed so firmly, without pressing them too much, that there is no danger of them shifting. A layer of the packing must be placed under and another over the fruit.—J. D. E.

4451.—Pollarding Apple-trees, &c.—Every thing would depend upon the condition and vigour of the trees. I have seen trees do well after and make fine heads. It is about on a par with re-grafting, and this result is in proportion to the vigour left in the tree.—E. H.

4456.—Best Strawberries.—Unless one is thoroughly acquainted with the soil it is best to plant for main crop only thoroughly reliable kinds, and these should include Sir J. Paxton and President. Vicomtesse de Thury is very valuable on indifferent soils and is a good fruit; Jane Veitch, very large; Elton's Pique, good late sort. Among more recent sorts Prince Teck, in the way of Sir J. Paxton but larger; Barnes' Prolific; Noble, very early; Waterloo, very large, are all good; and on good Strawberry soils I should always include British Queen.—E. H.

4515.—Myrobalan Plum.—This, which is also known as the "Mirabella" and "Myrobella," makes a fairly good fence, though I should prefer ordinary "Quicks" myself. It can be obtained of most nurserymen.—H. C. B.

You could not have looked through catalogues of leading firms, as the Myrobalan Plum is a common tree. It is also called the Cherry Plum, and its botanical name is *Prunus myrobalanus*.—O. T.

Prunus myrobalanus is sometimes called the Cherry Plum. Any nurseryman can obtain this, if he does not possess it, from the large tree and shrub nurseries in the country. It has been recommended for hedges planting, but I like the White Thorn better; it makes a neater and better hedge.—E. H.

Drawings for "Gardening."—Readers will kindly remember that we are glad to get specimens of beautiful or rare flowers and good fruits and vegetables for drawing. The drawings should be made with the best manner, and will appear in our course in **GARDENING ILLUSTRATED.**

HOUSE & WINDOW GARDENING.

AURICULAS FOR A WINDOW-BOX.

THESE fascinating little flowers, long forgotten and neglected, are now again in high favour, and collections of Auriculas are to be met with on all sides. Being perfectly hardy, they are equally suitable for a garden, a cold greenhouse, a glass porch, or window-boxes, in which they bloom during April, even in a north-west aspect, which suits them well. Auriculas are divided into two distinct families, the alpine Auricula and the Primula Auricula, the latter being the most suitable for growing under glass (without fire-heat), and the former, alpine Auriculas, the most useful for window-boxes. They can be procured in clumps during September, and planted in the box at once, using plenty of drainage at the bottom, with compost of turfy loam three parts, to one part of leaf-mould, and a sprinkling of soot and old stable manure. Auriculas should not have too rich soil, and must at all times have plenty of air. Their cultivation has been known ever since the beginning of the seventeenth century, when Clusius, a great Auricula lover of ancient times, wrote his "History of Rare Plants." Until of late years, however, the alpine Auricula has been neglected, although the Primula Auriculas were a perfect orna with our grandmothers, who were well acquainted with the four different types of these plants—i.e., green-edged, grey-edged, white-edged, and self, the last section comprising a number of beautiful velvety blossoms of purple, yellow, maroon, &c. Alpine Auriculas, on the other hand, are either edged with deep-brown or claret colour, the centres being yellow, or else the edge is purple, with a pale cream-coloured eye, and they bear but little farina on their leaves, the thick white pollen which covers the leaves of the Primula Auricula family being usually absent from the alpine, although there are now some hybridised varieties which also have whitish leaves. The outline of both kinds is very similar, and not in any way difficult, young plants being best procured as offsets, with a little root attached where it is desirable to grow them in pots, when they can be ranged in the front of the box (the pots sunk in Cocoa-nut-fibre or fine ashes), and potted in September, using small sized, and standing the plants in a shady place with a north aspect until they are established. They should not be too freely watered after repotting. The compost should be used in a fairly moist state and water withheld from the plants for two or three days, as they are otherwise liable to rot off. Covering them with a bell-glass during this time is a help to them, or placing them in a steady frame with the glass on, where they can have the damp air which they need to support their foliage until

for summer flowers. They may then be repotted, removing most of the old soil, and examining the roots carefully for any sign of decay, which should be cut out with a sharp knife, the disease being thus prevented from spreading. Auriculas should always be grown in small pots, and may often be repotted into clean pots of the same size they had last, dividing the clumps if necessary. They may also be planted out in moist shady borders for the summer, if a garden be available, and this is perhaps the best plan, as they ripen their crowns well here (if not allowed to suffer from want of water in hot weather), and can be potted up or placed in boxes in September, backed up by well-grown plants of English Ferns, such as Scolopendrium vulgare, and the handsome crested varieties of the Hart's-tongue, which can now be procured, alpine Auriculas make a charming window-box, being especially suitable for those aspects where other spring flowers are late in blooming.

L. R.

THE KITOERN GARDEN.

LAYING OUT A KITCHEN GARDEN.

4526.—In the absence of particulars as to site and size of the garden, I must assume a good deal in giving information on this subject. Presuming the garden is in the form of a square, facing due south, and has a wall or fence around it, the most convenient plan of arrangement is to divide the garden into four equal-sized parts, commonly called "quarters," if the garden is not more than an acre in extent. Assuming that the boundary is equal on all sides, a border 10 feet wide should be formed alongside the boundary. These borders are useful for growing small vegetables in, such as Carrots, Beet, Broad Beans, Early Potatoes, Dwarf Peas, and saladings, as well as providing space for the raising of plants for the flower-beds, such as Wallflowers, Forget-me-nots, &c., all of which need space. The border facing the north is most useful for many subjects. For instance, summer Turnips, extra late Strawberries, as well as a reserve ground for shrubs that may be required for filling the flower-beds during the winter months. Close under the wall affords a capital place for the growth of Mustard and Cress during the summer months. Next to this border should run a path 5 feet wide, and parallel to the border. Down the centre and along the top the paths should be at least 6 feet wide, if the garden is an acre or less in proportion. On each side of the centre path a flower-border might be made, in width according to fancy, the back of the border of say 6 feet wide might have a single row of espalier trained fruit-trees—say, Apples and Pears. Cross paths should intersect the centre one for convenience in working. In forming the paths both sides should be on the same level and parallel to each other. The bottom of the path should be of the same formation as the finished path, slightly higher in the centre and rounding to the sides. Whether the garden is on a slope or dead level the edges should follow the same rake. Before making the paths the edgings must be put down, no matter of what they are constructed. Box is the best of living edgings, when properly planted and regularly attended to in keeping it out short. A very neat and interesting edging can be formed with flint or other stones, planting Double Daisy, Pinke, Arabis, Sedum glaucum, S. Lydium, or Herniaria glabra at the back of the stones, allowing it to grow over them and thus form a living edging as well as being a showy one as well. Even strips of board made secure in the soil will answer the same purpose as the stones, but they do not give quite so nice an effect until the edging is complete. If there are no natural means of getting rid of surplus water from heavy rains drains must be laid. A single row of 2 1/2 inch pipes down the centre of each path, with small catch pits built at the side of the path and connected with a short length of pipe, will take away a quantity of water, and if these drains can be connected with a main drain at the lowest point in the garden, running into a tank or pond, the water will be useful. Not less than 3 inches of rough material, such as stones, broken bricks, or clinkers, will be necessary for the bottom of each path. Over this quite an inch of fine gravel should be laid and made quite smooth. Paths made in this manner are always dry and pleasant to walk

Fig. 2.—Pear "Duchesse d'Angoulême." (See page 400.)

the roots are able to perform their work. Failing a frame or bell-glass, they may be placed in a box with a few inches of damp coal-ashes at the bottom and covered with a piece of glass for a few days, after which they are best out of doors with their pots sunk in ashes in a shady window-box. The plan of growing them in pots has the advantage, that they receive no check in flowering in April, although it is necessary to remove them in May when the box is wanted

URBANA-CHAMPAIGN

upon. All the garden intended for cultivation should be trenched 2 feet deep, rotating the surface-soil still at the top, and returning that from the bottom of the trench to the same place again. The management of the different kinds of fruit depends so much upon circumstances. Presuming there are walls, those facing south will be the most suitable for Peaches, Nectarines, and Apricots; Pears and Cherries succeed in a western exposure; Plums grow admirably against an eastern wall; around the edge of the quarters small fruit, such as Red, Black, and White Currants and Gooseberries, may be planted 4 feet from the edge of the path, planting a bush Apple-tree every 20 feet. Strawberries should occupy a position on one of the quarters, and so should Raspberries, choosing the most damp corner for the latter. Permanent crops, like Rhubarb, Asparagus, and Sea-kale ought to occupy one quarter by themselves, as this plan leaves the three remaining quarters free for rotation cropping of such vegetables as Potatoes, Peas, Cabbage, Winter Greens, and root crops. As it is not wise to follow a crop of Cabbages with another of Brussels Sprouts, for instance, if the three quarters are left entirely free from permanent subjects this repetition of cropping may be avoided. In a short article like this it is impossible to deal so fully with this subject as it deserves. More than a general idea cannot be given; particulars as to details of any one point would be freely given by permission of the Editor.

— You send so little information to guide one in giving you an answer, that only general principles can be referred to in doing so. As a rule, it is best to keep vegetables and fruit as distinct as the circumstances will permit. That portion of the space set apart for fruit should adjoin the lawn or pleasure grounds, so that the passage from one part to the other should be less objectionable than leaving the flowers and plunging at once amongst the Cabbages and Potatoes, assuming this inquiry to refer to a garden of only moderate dimensions. The portion intended for fruit should be the whole of the width; then should follow lines of pyramid or bush-trees of Apples, Pears, Cherries, and Plums. Next to these should be lines of Gooseberry and Currant-bushes, and to follow these may come Raspberries, and then the Strawberry-beds. For still smaller gardens a line of espalier-trained Apple or Pear-trees makes a good dividing line between the flowers and vegetables. The middle portion of the space should be occupied with such vegetables as Onions, Carrots, Cauliflower, Beans, &c., and such subjects as Asparagus, Sea-kale, and Rhubarb should be located at the farthest end. With regard to the direction of the beds I like the rows of the different crops to run north and south, and in laying out a new garden it is easy to arrange for this being done. Good gravel is the best material to make the walks, and a well kept Box-edging is superior to everything else need for that purpose.—J. C. C.

TURNIP CULTURE.

TURNIPI may be had in good condition nearly ten months in the year by sowing a little seed at various times from the first week in March to the last day in July. A light gravelly soil, well broken up, is that which is most favourable to the production of good Turnips, but they will succeed in all sorts of soils if properly prepared. Gardens that are situated somewhat low and moist, with moderately rich, well-cultivated soil, will produce early Turnips of the best quality, though such gardens are unsuitable for the generality of spring crops. The first crop should be sown about the last week in March, in an open situation, where the ground is light. When sown two or three weeks after midsummer, and the plant becomes established, there is no difficulty in securing a crop on tolerably well-managed land. Others to succeed those sown the previous month should be put in about the end of April. This crop will be ready for use by the end of June; those sown at the end of March, if they escape the flea, will be ready for use by the first week in June. Another sowing should be made early in June, and a sowing for the main crop about the first week in July. In all cases locality must decide the time to sow the last crop. As a rule, large Turnips are not required; therefore they should be sown just soon enough to insure roots about the size of one's fist. It

is a good plan to make two sowings at an interval of a fortnight from each other. Turnips are in all cases best in drills about 1 inch deep and 14 inches apart. Late crops should be sown rather wider apart than earlier ones, in order that light and air may circulate freely among the foliage and about the roots, otherwise the leaves get watery and incapable of resisting severe weather. As soon as the plants have made leaves 1 inch in width, the hoe must be at work amongst them, cutting up weeds and stirring up the ground. They should be thinned to about 12 inches from each other in the row. In dry weather give them a good soaking or two of water, and hoe between the rows at least once a week. I ought to have stated that it is not essential that the ground should be prepared just previous to sowing the seed, it being an advantage to have it prepared some time beforehand, when it is not required for other purposes. In all gardens of limited dimensions every inch of ground is an object, and the moment one crop is gathered the ground should be turned up and planted with another. Manure freely and dig deeply, and the soil will be capable of bringing to perfection, two, three, or even four crops in one season. For early sowings of Turnips, the best are early American Stone Strapleaf, which is very early and good; Early White Dutch, a sort that becomes quickly fit for use; Early White Stone; and Early Snowball. For the main crop there is nothing better than Red Globe; it is an excellent variety, and it has the good property of remaining a long time fit for use, and also a good mid-season kind in the one here figured, Yellow or Golden Maltose Turnip.

Turnip "Yellow or Golden Maltose."

For late winter use Orange Jelly and Chirk Castle are fine hardy sorts; the flesh of the latter is beautifully white, though the outside is nearly black, and the flavour is good; but the flesh of the former is yellow, and, therefore, to some objectionable. The greatest enemy to the Turnip crop is the fly, which is most to be feared in fine, sunny seasons; heavy rains and cold springs destroy them. One remedy is to dust the ground all over with quick-lime as soon as the plants appear above the surface; this, in most cases, is effectual. Some apply gas-lime three or four days after sowing the seed; sifted wood-ashes, put on as soon as the plants show their seed-leaves, have also proved an effectual remedy. R.

4463.—Seed from Tomatoes.—Choose medium-sized, perfectly formed fruit of any kind, wait until they are perfectly ripe, then cut them in pieces, taking out the seed along with the pulp, place it in cold water, washing the seeds free from all flesh and juice of the Tomato. Lay them thinly in a dry place for a few days until they are thoroughly dry, then they are ready for storing.—S. P.

4531.—A small greenhouse.—A Vine could certainly be successfully cultivated in such a structure as the one described, even without the aid of any artificial heat. I should certainly recommend a Black Hamburg in preference to any other, especially if the local climate is fairly warm, and the situation moderately sunny and sheltered. Otherwise a Royal Muscadine or Buckland Sweetwater should do well. I do not know exactly what the gas-stove mentioned is, but personally have a strong objection to the consumption of gas inside a plant-house in any way. A flue would probably be more suitable,

and certainly less costly as regards fuel; if gas is used at all it should be in a properly-constructed stove with a boiler, in connection with about 25 feet of 3-inch piping. A Vine, however, does not need any artificial heat during the winter—in fact, it is better without it, most decidedly, and a heating apparatus would only be necessary if you wish to grow any tender plants in pots, &c., as well. In a totally unheated greenhouse attached to a small residence near here a really magnificent crop of Black Hamburg Grapes has already been ripened, though, of course, this has been an exceptional season: but with a sunny south aspect there need not be many failures.—B. C. R.

INDOOR PLANTS.

4523.—An Ivy-leaved "Geranium"—Your Ivy-leaved "Geranium" is, I expect, Madame Creusse. I grow it largely for supplying cut flowers in winter, and always pruned rather hard back about May. If out back now, unless in a very warm house, there will not be many flowers in winter, but all dead wood should be removed now, and the young shoots trained in. Give liquid-manure for three or four weeks twice a week.—E. H.

—Pick off all dead leaves and flower-stems, and tie the shoots either to the wires which support the branches, or to the latter themselves. So much more blooms will be had from the plant next year by following this treatment than though it was cut down to within three or four feet of the ground. The Ivy-leaved "Geranium" does not break readily into new growth like an ordinary "Geranium" of the Zonal section. I have some plants treated in the way recommended, and they have been in their present position for the last fourteen years. The well is 12 feet high and thickly covered.—S. P.

4503.—Compost for the Oleander.—The Oleander thrives well in a soil composed of two parts peat, one part loam, and a fair proportion of sharp silver-sand. It is most important to provide good drainage in the pots, as the plants require a large quantity of water. The reason why the Oleander presents such an unsatisfactory aspect in the majority of gardens is because they are never or seldom shifted into large pots, but kept stoving in the same size from year to year. Another fault is in not giving sufficient heat during the growing season, so that the flowers can expand well. Oleanders are often grown in rooms, but they are not good plants for the purpose, as the temperature is too varying, and artificial warmth is required.—C. T.

4527.—A span-roofed greenhouse.—The proper place for a boiler will be a point between the greenhouse and coach-house, and on the same level as the latter, or, if possible, slightly below. Preferably it should be placed in a small, separate shed or the like, so as to avoid dust, &c. For a propagating house of the size named about ten rows of 4 inch piping would be required, equalling 200 feet altogether, and with a few feet for the coach-house a boiler capable of heating 250 feet to 300 feet should be employed. A small plain Saddle, set in brickwork, would do, or one of the larger sizes of the upright independent slow-combustion description would come cheaper as well as require less attention, and consume little, if any, more fuel. As the pipes in the propagating-house will be on a considerably higher level, a valve must be placed in the flow thereto, in order to check the current and throw some heat into the coach-house.—B. C. R.

—There is no difficulty in heating the coach-house and greenhouse from one fire. Fix a dome-top boiler in the coach-house, and carry pipes from it up into the greenhouse. You will probably get all the warmth you want to air the coach-house when you want a fire for the greenhouse. It will be better, however, to be able to heat the two structures separately, in case it should be wanted. A flow and return pipe along the back and two ends of the coach-house will be sufficient, and the same quantity of piping will do for an ordinary greenhouse of the size you mention if the pipes are 3 inches in diameter. If you heat separately you will want feed-cisterns in both buildings and valves in both sets of pipes to turn off and on, the cistern

In each case being above the highest point of the pipes.—J. C. C.

4521.—**Begonias after flowering.**—You have done wrong. The Begonias were not ready for ripening off, and their beauty must have been very short-lived. It is a common but great mistake to withhold water until the tops have quite died and the water must be withheld gradually, otherwise too great a check is imposed. It is too late now to do much good, but treat the others as advised. When they have quite died down, then lay the pots on their sides, under a greenhouse stage or similar place, where they will not be exposed to drip or frost. In the spring, when commencing to grow, take them out, re-pot them, and start in gentle heat.—C. T.

—These plants should not be dried off immediately they are done flowering. Water should be gradually withheld by not giving them so much, and gradually reducing the supply; when the leaves assume a yellow tinge the plants of the tuberous varieties should have no more water until they are started again in the spring. Amateur cultivators and some gardeners have very crude notions about "drying off" plants. It is necessary to observe when the plants get to the stage when they may be dried off; and that is easily ascertained by the change in the wood or leaves.—J. D. E.

—The plants have been put on the stage too soon. Take them out and stand them on ashes in a sheltered and sunny spot out-of-doors, giving a very little water as long as the leaves remain green, and gradually withholding it as they turn yellow and fall. This treatment will mature the growth thoroughly, and render the tubers sounder and larger than any other method. Bring them inside before there is enough frost to penetrate the pots.—R. C. R.

4503.—**Tree Carnation outtings.**—Cuttings of lady firm shoots of Tree-Carnations will strike now in a frame. I should dibble the outtings in pots in sandy soil, which should be kept in a moist condition, and be shaded from bright sunshine.—E. H.

—I am now busy striking Tree-Carnation outtings; it is not too late, but to make sure that they will strike a little bottom-heat is necessary. Mine are treated in this way. I have a low pit to spare, unheated, and I put in about two barrowloads of stable-manure in one corner of the pit. Some Cocoa-nut-fibre or spent tan is put over it, and a couple of hand-lights. I use for the cuttings small 60-sized flower-pots. They are well drained and filled with fine sandy soil. The small side outtings are best, and seven of them are planted in each pot. They form roots in two or three weeks. They must all be struck in the same way.—J. D. E.

4182.—**Creepers for a small greenhouse.**—The best creeper or climbing plant for a greenhouse is the white variety of *Lapageria rosea*. The second best is *Lapageria rosea* itself. Some varieties are much better than others.—J. D. E.

4519.—**Malmesbury Carnations.**—The best compost for these is a mixture of good turfy loam four parts, one part each of leaf-mould and very old hot-bed manure, one part of burnt earth, plenty of sharp sand, and a dash each of soot and Thomson's or other good artificial manure. Drain well and pot firmly. But for water flowering they ought to have been established in the pots some time ago. In winter they prefer a temperature of about 55 degs., with free ventilation on all fine days, and a dry rather than moist atmosphere. Keep them also near the glass, and water only when really necessary.—B. C. R.

—These do not flower so freely or so well in the winter as the Tree-Carnations. To get anything like a good bloom in the winter strong plants should be grown, struck from cuttings or layers early in the year, and grown on in pots to be planted in their flowering pots at the latest in September. Use good yellow loam, leaf-mould, and decayed stable-manure, with a little sand added. The plants should be placed near the glass in a heated house; but the atmosphere of a fernery would be too moist for them. The vinery would be better.—J. D. E.

4523.—**Cleaning Camellias.**—The Camellias are infested with white scale, which is worse if such a thing is possible—to get rid of them meansy-bag. Every bit of the plants, wood and foliage, must be sponged over several times with a strong solution of Glucon Compound, 4 oz. to the gallon, used warm; use a brush for the hard wood.—E. H.

—The plants should be thoroughly dressed with soft-soap and water, Tobacco-water, or some such preparation as *Picreol Oil*, which is an excellent remedy for the scale, evidently smothering the insects, and doing so thoroughly, working the brush well in at the joints and corners where the pests congregate.—C. T.

RULES FOR CORRESPONDENTS.

Questions.—Queries and answers are inserted in *GARDENING* free of charge if correspondents follow the rules here laid down for their guidance. All communications for insertion should be clearly and concisely written on one side of the paper only, and addressed to the Editor of *GARDENING*, 37 Southampton-street, Covent-garden, London. Letters on business should be sent to the Publishers. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Unanswered queries should be repeated. Correspondents should bear in mind that, as *GARDENING* has to be sent to press some time in advance of date, they cannot always be replied to in the issue immediately following the receipt of their communication.

Answers (which, with the exception of such as cannot well be classified, will be found in their different departments) should always bear the number and title placed against the query repeated, and our readers will greatly oblige us by advising, as far as their knowledge and observations permit, the correspondent who seeks assistance. Conditions, soils, and manures vary so infinitely that several answers to the same question may often be very useful, and those who reply would do well to mention the localities in which their experience is gained. Correspondents who refer to articles inserted in *GARDENING* should mention the number in which they appeared.

4533.—**Bottling Grapes.**—How is this done, and how long will they keep? Will some reader kindly reply?—HAMBOURGH.

4530.—**Treatment of Nut-trees.**—Will someone kindly inform us as to the management, pruning, and growing, &c., of Nut-trees?—M. N.

4540.—**Oleander.**—What are the best—1, White and 2, the most profuse flowerers; 3, and bearing the largest flowers?—HILSONVILLE.

4541.—**Removing old tree stumps.**—Will someone kindly inform me of the best way to root out old and decayed tree-stumps on a meadow or field?—M. N.

4512.—**Raising Quail.**—Will someone kindly tell me if there is any plan by which Quail can be raised from hatched in one year, or other wise the best plan to raise it?—E. C.

4513.—**Neapolitan Violets.**—I want to start a bed of Neapolitan *Viola* Vicia. Will someone kindly tell me how I should proceed, and what sort is the best?—AMSTERDAM.

4514.—**Fowl manure.**—Will someone kindly tell me what plants in good putting of winter manure, and those that will grow with it, and if I must mix it with anything else?—E. J. H.

4545.—**A fine Snowdrop.**—I have growing in my garden a Snowdrop 15 feet high, the stem is 6 inches in circumference, and I would like to know if this is not an extraordinary flower?—R. WILSON.

4516.—**Roses from outtings and seeds.**—I should be glad if anyone would give me some little information concerning the method of raising Roses from outtings, and seeds?—E. BUNNERS.

4547.—**"Thrips" on Vines, &c.**—Will someone please tell me the best way to clear Vines with fruit on, all size or nearly ripe, of "Thrips," also on plants in same houses, such as *Fuchsia*, &c.?—W. H.

4543.—**Bedding "Geraniums."**—Will someone please tell me the best bedding soil, and also give the names of a few other good ones for bedding?—W. H.

4540.—**Elagnia ocaprolata.**—Is there any chance of flowering the plant in a pot, or must it be planted in a bed in a greenhouse? It makes rapid growth, but has never flowered, though in my possession for three years.—K.

4550.—**Saving Cucumber-seed.**—I should be very much obliged if anyone would inform me how to save seed from Cucumbers growing in a greenhouse? I have two turning yellow. Did I ought to put them to rest on anything?—DORRAGON.

4551.—**Tortoise stove for greenhouse.**—Will someone kindly tell me if a Tortoise stove combustion stove, and of what dimensions, would be suitable to heat a lean-to greenhouse facing east, 7 feet by 8 feet, to give a temperature of 60 degs. in winter?—A. O. G.

4552.—**Snails in a garden.**—Please tell me how to get rid of snails? They crawl all over my carpet in the night. I have a depth of 18 inches under my floor. I have stopped holes where I thought they come, but they leave their slime over everything.—CONSTANT READER.

4553.—**White Thorne from seeds.**—Would anyone please to give me any information as to when would best be the time to plant seeds of White Thorn? And also which would be the best way? And also how long would they be before coming through the earth?—H. H.

4551.—**Heating a greenhouse.**—I have a lean-to greenhouse, one of the cheap ones. Will someone recommend me the best paraffin stove with hot-water pipes to set for it? The size is 12 feet by 8 feet. Best of thin glass, will require a good deal of heat.—AMATEUR.

4555.—**"Geranium" outtings.**—Will anyone kindly let me know if I can have "Geranium" outtings over the winter in a cold frame used for growing Cucumbers in summer? If so, please suggest how, also best remedy for keeping the leaves from damping off?—JONAS.

4556.—**Evergreen creeper.**—Will any person kindly let me know the names of six or eight evergreen creepers, to grow at the south side of my house wall, 30 feet high, and to flower in spring or summer, something worth looking at? Also say when to plant and best soil?—JONAS.

4557.—**Tobacco.**—I have lately been drying leaves of the Tobacco-crop by hanging them on string in rows in a tent. Will someone tell me what must be done to get the leaves into condition for smoking in a pipe? I collect the culture has been tried in England with some success.—F. C.

4558.—**Evergreen hedge.**—Will anyone please to let me know what to plant at the north and east side of a forest to hide an unsightly underwood, something that will make a thin evergreen hedge about 6 feet or 7 feet high? I was thinking that Privet would be a quick-growing stuff.—JONAS.

4550.—**Heating a greenhouse.**—Which is the best system of heating a greenhouse, size 25 feet by 14 feet, span-roof, brickwork, in which are two Vines? I wish just to keep out frost, and I should prefer a system that needs attention once in twelve hours only. Will some reader kindly advise?—AMATEUR.

4530.—**A greenhouse for profit.**—I have a conservatory 25 feet long by 10 feet broad, heated with hot-water pipes. There are two Vines and a few flowers in it. I should like to make it profitable this winter if possible. Would anyone kindly advise me what to grow? I had an idea of forcing Rhubarb.—AMATEUR.

4561.—**Tea-Roses.**—Would anyone kindly give me the names of 24 additional Tea-Roses suitable for outdoor culture with flowers having erect habit? In autumn I intend planting outside three dozen Tea in a sheltered position on west-coast of Scotland, and I wish to be advised of the very best varieties to select.—DANIEL HILL.

4502.—**Unhealthy *Fuchsias* and Ferns.**—Will someone kindly tell me what the disease is that my *Fuchsias* and Ferns are affected with? They are covered with small, light-coloured insects, and are full of black spots, which causes them to turn yellow and fall off. What will be best to do with them?—J. S.

4563.—**Management of Pear-trees.**—I shall be glad of information concerning the management of Pear-trees? I have three trees in a well-cultivated garden, growing on walls. Every other fruit and vegetable has been very prolific. These trees have never borne much fruit. This year two of the trees have one Pear each, and the other tree two Pears. How is this to be accounted for?—A. L., Rugby.

4564.—**Feather eating.**—My fowls (*Game*), both some of the cockerels and pullets, eat their feathers. They are in a field, with plenty of Grass and Heath. They have as much soft food as they can eat in the morning, consisting of ground oats and "thrice," with scraps of meat and vegetables and Corn—Wheat—in the afternoon. Will "Doulton" kindly advise me? The grit in the field is like small portions of granite.—CHURTWAD.

4505.—**Catching Rabbits.**—I shall be very glad of suggestions for catching Rabbits, which at present destroy the plants in my garden? I have put wire-netting round each bed, but the Rabbits either get through or under it. As my garden adjoins a wood which swarms with them, I fear the plague will always continue. I cannot shoot the Rabbits, so should like to hear of some trap or net that would either catch them alive or kill them at once, without torturing them as the ordinary trap does.—HUMANE.

4556.—**Treatment of *Hippocrepis* snipe.**—Having had some bulbs of this plant sent me from Ceylon, I shall be glad of some information about treatment, as though I have had them four years there is no sign of their coming into flower. The plants are not healthy, but have not increased in size at all. When first bought they had increased in size at last, past, and leaf-mould, walk out of the pot, and put into vinery heat. Why do they not give increase or flower, as the bulbs are of a fair size?—VINA.

4507.—**Violets in frames.**—I shall be obliged if anyone will inform me the best mode of obtaining Violets in frames during winter? Last winter I grew them in pots and they were a failure. In the spring I removed the plants into a wire border. Should I this autumn take only the runners or the whole plant with runners included? I propose to plant them in the frame without pots, and shall be glad if you will kindly give me information as to soil, culture, and general management? I have a *Marie Louise* and *Comte de Brazza*.—F. K. J.

4563.—**Climbing Roses.**—Would "J. O. C." or someone else please to give me a little information? I have a span-roofed greenhouse, 24 feet by 10 feet, ends stand east and west, and it gets the sun all day. I have two Vines on the front side. I should like to have the remaining part of the Climbing Roses. If the house is suitable? Would the Roses on the front side be better placed in an outside border? Would back side be better placed inside the house? How many plants, and what kind are best for wearing purposes? How to prepare the soil? Present soil very light. Could I do without additional heat?—NOVICA.

4569.—**Cabbage growing.**—Would someone kindly tell me how to cultivate ground for Cabbage? After I took up my early Potatoes I set out some healthy Cabbage-plants, and for some time they went forward splendidly. Now, just when they are beginning to heart, they have all turned yellow, and are dying away, and I have pulled some up, and I find the root very large—what is termed stubbed—also with wireworms attached. Would someone tell me a way to stop them? I may say Potatoes have been the only vegetables grown on the ground before. The soil is stiff, but sandy, and excellent for Potatoes.—E. J. H.

4570.—**Gloriosa superba.**—I had a splendid bulb of the above sent to me straight from India last winter. I potted it as directed in sand and leaf-mould, giving very little moisture, in March, in a forced vinery. I removed later on to a bottom-heat in frame, and was told to expect it to bloom in autumn. As yet there is no sign of growth, either root or leaves. Can anyone suggest a cause, as the tuber looks sound and plump as when I received it? Is it a plant that is likely to rest a year, as I have experienced some other bulbs do, as *Fritillaria persicum* and *Kemischaticum*? What am I to do with this winter? Remove it from pot and re-plant next March or leave it in the same pot till it starts? Any advice will oblige.—VARA.

4571.—***Physanthus albens*.**—I bought some seeds of this about seven or eight years ago, and succeeded in raising some plants, one only of which I kept for my own pleasure. I grew them on until I had it in a 5-inch pot, well filled with roots; but not a single flower was to be seen. I got nearly sick of it, the more so as I was led to hope for something especially beautiful, "rivalling even the *Staph. maculata*." I was tired of giving it house room, so in the spring, when the frost had gone, I planted it out-of-doors without caring whether it lived or died. However, to my

surprise it has taken kindly to the change, has grown more in the last few months than ever it did before, and best of all there is no flower-bud in almost every joint, so now my hopes are raised again. I should be glad to know if it would be safe to leave it; out-of-doors all the winter. If not, what can I do with it?—J. H. BARN.

NAMES OF PLANTS AND FRUITS.
Names of plants.—B. C. P.—Cissampelos cernuum, W. W.—Ivacoate Dactyloctenium.—L. B.—1, A Cypripedium, like C. Plicatarianum; 2, Cypripedium Godefroyi, not C. bellatulum. F. G.—Oncidium Jonesianum.—W. ROSES.

SEASONABLE NOTES.

It will be well now to look over any notes taken down at the various Rose-shows of the year, as where choice or new varieties have been noticed an early order is generally necessary if good plants are to be secured. At the same time I would earnestly advise my readers to look up the habit of any variety fresh to them. If not of vigorous growth, be chary of purchasing it. We have such a vast variety of really grand Roses, and of almost all shades, that a new one, unless most distinct and of good growth, is hardly worth purchasing and risking disappointment. The past summer has been peculiar in several ways, and many Roses that were once almost discarded have come to the front, and we need to be careful and shy of growing these one-season Roses. Then, again, there have been splendid examples of Horace Vernet and Duchesse de Bedford exhibited on almost all stands; but for the average grower these two varieties are useless compared to others, which nearly approach them in all but weak and uncertain growth. To the exhibitor they are indispensable, while they are much too uncertain to plant for garden decoration alone. I have been much struck with the serenity of such Roses as Comtesse de Serenyi, Duchesse de Valombrosa, and Madame Lacharme. One would have thought the past summer an ideal one for these double and light coloured varieties, yet I have not seen a good bloom of either, although I grew some hundreds of each, and have attended a large number of the principal Rose-shows. No doubt there will soon be many queries to hand respecting Rose planting, now that the proper season is close upon us. Anticipating these, I propose to give a few hints forthwith. Wherever possible endeavour to plant some time during October. This year almost all plants will be in grand condition by that date. I have more than once called attention to the rapidity with which Roses make new roots when lifted and laid on one side for a few weeks. It is self-evident that these would be of much more service if made in the plants' permanent quarters, as however carefully the plants may be lifted the second time a large number of these tender roots will be broken. Unless transplanted early, we do not get many of these roots, and I am quite certain that a good lot of these is almost equivalent to the Rose being established a season. Both the Hybrid Perpetuals and Teas will be in a fit condition for lifting by October. My plants of the former are already fit, and I am contemplating lifting a batch for potting up to throw early bloom under glass, a few notes upon which shall appear shortly. Teas and Noisettes, growing so much later than the majority of the Hybrid Perpetuals, may be lifted a little later on. But if we were to wait until all of their wood was ripe we should find ourselves into mid-winter. Some of the wood is sure to chivel upon autumn-planted Teas and Noisettes; still, I would prefer to plant now than during December. If not then wait until February or March.

MANURES.—Now a few words about soil and manure. I have frequently tried to point out how close a bearing these have upon one another. A manure suitable for a light soil is not equally so for the opposite. If your ground is stiff, apply horse-manure, soot, leaf-soil, and old decayed vegetable refuse. The clearings from road-sides are also very beneficial, as they contain a large amount of grit, which tends to keep the soil more open. On the other hand, if the soil be light, avoid all of the above, with the exception of decayed vegetable refuse and weeds. This is excellent for all soils. Should the soil be very light, it is well to get some stiff loam; the stiffer the better, so long as it is not clay. Turn the stiff soil into a lump, and incorporate a fair amount of cow-dung, pig-manure, and any stimulant of a stiff and close nature. When this is applied, it will bring your soil into much better heart for Roses.

STOCKS.—This is always an important question with the amateur, and one upon which a great divergence of opinion exists. I have tried them all, and under different conditions; here is the result of my experience, extending over twenty-five years. Use the seedling Brier for Teas and Noisettes upon deep soils, especially if they be somewhat stiff. The cutting Brier is better for shallow soils, and also for these sections of Roses in light ground. All Teas and Noisettes will thrive upon the Brier in any form, whether seedling, cutting, or hedge Brier in the form of short etardards. I much prefer the latter for these varieties whose blooms have a drooping tendency; Niphotos and Souvenir d'un Ami may be quoted as examples. Grown as dwarfs from the ground, these, and similar kinds are often spoiled by rain and dirt; but on a Brier of about 2 feet they escape this to a great extent. Briars are also good for all Hybrid Perpetuals, Bourbons, and Hybrid Teas; but the Manetti is considerably earlier, and upon light soils is equally suitable for most of the best three sections or classes of Roses. A few of the most notable exceptions are Captain Christy, Marie Verdier, Louise von Houste, Sultan of Zanzibar, and Her Majesty. It is safest to avoid the Manetti entirely when growing Teas, although a few, like Gloire de Dijon, &c., will thrive well on it. A curious fact is the grand way in which some of the Dijon Teas will thrive on this stock, and yet others will not. For example, Kaiserin Friederich likes it, while another Dijon Tea, Bouquet d'Or, abhors it. The Manetti is, as before remarked, considerably earlier than the Brier; but it is not quite so constant in growth, nor does it produce blooms so late as the latter. For pot culture, I prefer all classes, Teas included, to be grafted upon the Manetti.

The POLYANTHA is also a useful stock, but I do not think it is any improvement upon the Brier. For a few of the extra strong growers, especially in shallow soils, I would rather have them worked upon the De la Oriferales, a stock which produces more sap than the Brier, and consequently can keep up the supply so necessary to the extra vigorous varieties. I also find that William Allen Richardson, Bouquet d'Or, and Maréchal Niel form a more complete stock with this than with any other stock. During October it will be well for my readers

readers, who like to grow their own Roses from the first stage, to propagate a few stocks of the Brier, De la Oriferales, and Manetti. They are readily struck from cuttings, made 6 inches to 9 inches long, and inserted in sandy loam.
P. U.

4508.—**Climbing Roses.**—As you have a couple of Vines on the front roof of your house, and it is only 24 feet long, you will have room for no more than one Rose at each end on this side. On the back side you may plant four or five. As you are using no artificial heat, the Roses may be planted and treated exactly the same as the Vines. What will suit one will be equally suitable for the other, but insect pests will trouble the Roses most. The necessity of keeping these down is rather against the Vines when fruit is showing. Make your soil heavier by adding pig-manure, also a little very stiff loam. I should choose the following six varieties: W. Allen Richardson (orange), Climbing Perle des Jardins (yellow), L'Idéal (metallic red and copper), Reine M. Henriette (red), Mme. Chavry (rich salmon), and Climbing Niphotos (pure white).—P. U.

In a house with such capital dimensions you ought to be able to grow Roses and Vines together with a fair amount of success. You had better not attempt too much. The front side should be confined to the Vines only, and Roses on the other side, and the border for these should be inside the house with the entrance exposed to the light. For a length of 24 feet four Roses will be sufficient to fill the space. The sorts may be Maréchal Niel, Climbing Niphotos, General Jacquemont, and Climbing Devonshire. The last mentioned should be cut down at the end of the first year to within 1 foot of the border if it has only a single stem, the object being to secure two or three main branches, which will reduce the vigour and enable you to confine the branches to a smaller area than can be done when only one is left. Treated in this way a plant will last for a number of years, and be in flower more or less all the summer. You had better take away half of the present light soil—the lower half—to the depth of 2 feet, and make good with the same quantity of heavy loam, and instead of using animal manure, secure half a cwt. of crushed bones to mix with the soil. If you can allow a width of 4 foot from the border do so by all means, but 1 foot less will do fairly well. You can do without artificial heat for the Vines and Roses, and grow a few tender plants during the summer; but if you wish to cultivate the latter throughout the year, you will require artificial heat during the winter.—J. C. C.

4561.—**Tea Roses.**—You ask for the names of an additional twenty-four varieties. As you do not give the names of those you already possess, it may be that I shall name several of them in the following list. If so, and you will state them in another query, I will gladly replace them with others of an upright habit. You are wise in choosing those of the latter form, as they are much more exempt from dirt, and also show their beauty more prominently: Amzone, Anna Olivier, Catherine Marnet, Cleopatra,

Dovoniensis, Dr. Grill, Ernest Metz, Edith Gifford, Innocente Pirola, Luciole, Mme. Falcot, Mme. Hoste, Mme. Lombard, Perle des Jardins, Safrano, Isabella Sprunt, Souvenir d'Elise Vardon, Pauline Labonté, Souvenir de Paul Neron, Sueset, The Bride, Mme. Charles, Souvenir de Thérèse Levat, and Comtesse de Naidailac.—P. U.

— It is not likely that any two growers would recommend the same varieties for this purpose. I shall, however, give you the names of those which I either am growing myself or have soon doing well in other places. My choice would be: The Bride (this is a much hardier Rose than its appearance indicates), Grace Darling, Vicomtesse Folkestone, Speciose, Princess of Wales, Marie Van Houtto, Mme. Lombard, Mme. Eugénie Vordier, Mme. de Watteville, Comtesse de Naidailac, Anna Ollivier, Perle de Lyon, Mrs. James Wilson, President, Safrano, Jules Finger, Catherine Mermet, Letty Colas, Dr. Grill, Françoise Krüger, Gobault, Lady Mary Fitzwilliam, Mme. Charles, and Camoësa.—J. C. C.

4546.— **Roses from cuttings and seeds.**—It would have been better if you had started the former method of propagation a little earlier; anyhow, no more delay should occur. Proceed as follows: In the first place, do not work any hut strong and free growers. Choose wood a little over three parts ripe; that from below a flower just past its beauty is generally in a good stage. Make the cuttings 6 inches to 8 inches long, and insert them in sandy soil on a warm border, affording them an occasional sprinkle overhead and slight shade from midday sun. This is for outdoor striking. If you have a frame or pit make the cuttings smaller, do not remove any of the foliage, use a sandy compost of leaf-soil and loam, no manure, and keep them close in the frame, sprinkling them overhead occasionally. If you have neither pit nor frame, but possess a small greenhouse, place the same cuttings in pots or pans, the former preferred. Stand the pots in a box, cover over with glass to keep them close, and let the box be upon the floor or in some cool corner of your house. As the cuttings make roots gradually remove the glass until they can stand the full air of your house. When this stage is reached pot them off singly into small pots of the same compost, and stand them back in the box for a short time, keeping them close for a week or so and then gradually removing the glass again. After this they may be treated the same as other Roses and either grown in pots or be planted out in the spring. Seedlings are best if raised in boxes under glass in the early spring. Use the same compost recommended for cuttings, filling the box about two-thirds. Sow thinly, cover the seeds about twice their own diameter with soil, and then place a sheet of glass over all and stand them in some fairly warm corner. It is well to make the soil fairly moist at first, and then to keep them dark until the seed germinates. If you prick them off while in growth great care will be necessary. Hence the advice to sow the seed thinly, as you can then leave them to grow in the box all of the first year, it being much safer to move them when dormant. They may either be grown on in pots or planted out into a small bed of prepared soil. As a few seedlings ever prove worth the room I prefer the latter plan.—P. U.

— With regard to the cuttings, you had better wait until the middle of October before you insert them, and then have a bed of sandy soil made up in a frame to receive them. Have the soil fairly dry and made quite firm; into this fix the cuttings quite firm, 6 inches apart. Get the cuttings from the current year's growth, rejecting the soft tops and hard bottoms of fairly strong shoots. After the cuttings are put in, water well, and then put on the light, and let the frame remain closed all the winter, except to moisten the soil when necessary, and to remove any dead leaves. Protect the frame with mats in time of severe frost, and in mild weather—in March—commence to give a little air, at the end of May removing the lights altogether. With regard to the seeds, collect the hips about the middle of November, and place them in a flower-pot and cover them with sand. During the winter stand the pot on the floor of a cellar or cool shed. Next March take the seeds out of the hips and sow them thinly and deep in pans of soil; the pans being at least 6

than 6 inches in depth, and then the seedlings can remain in them until the following spring, when they can be planted out in the open. It is best to keep the pans under glass the first year, not necessarily in a greenhouse; the protection of a pit or frame will do. If you have many seeds they may be sown in well-prepared ground in April. In that case the young plants require to be taken up in the autumn and protected from frost until the following May.—J. C. C.

— Roses are frequently raised from cuttings, some varieties from roots much more freely than others; and the best time to put in the cuttings is when the young wood is nearly ripe. I have been more successful by taking cuttings from pot Roses early in August. The young wood is taken with a heel attached, and the cuttings are made about 4 inches or 5 inches in length; plant them firmly in flower-pots filled with fine sandy loam; cover them with a hand-glass or a close frame. If they are planted in the open garden October is the better month. Seeds may be sown in beds in the garden after they have been cleaned from the fleshy substance; they do not all come up in the second year after sowing.—J. D. E.

GARDEN WORK.*

Conservatory.

It will soon be necessary to use a little fire-heat on cold nights if the house contains many valuable specimens, especially if Kentias and other choice Palms are grown, but do not use more fire heat than is necessary to keep the night temperature about 50 degs, at night, and if the thermometer does not fall below 50 degs. without fire-heat the fire need not be lighted. Hard-wooded plants ought to be under cover now. These always do best in a house by themselves, where the temperature, ventilation, &c., can be made suitable to their wants. We are sometimes compelled to grow soft and hard-wooded plants in the same house, and we occasionally meet with men who succeed in doing things well under such conditions, but they are heavily handicapped where the two classes of plants are mixed. The conservatory, properly speaking, is the show house, where all plants in bloom may for the time being mingle together, but during the growing season they should, if possible, be kept separate. A light weak liquid manure occasionally will benefit Camellias now, and if the plants are heavily budded some of the buds should be thinned out; the flowers will come finer, and the strain upon the plants will be less. Large specimen Camellias are very useful for furnishing large houses. They form grand background and centres, round which other plants can be grouped, but Camellias are not of the same order. Ladies say they are so stiff and formal, and the prevalent taste is in favour of lightness and grace, and fragrance is especially valuable in flowers, and this the Camellia lacks altogether. Genias are valuable for winter flowering. I have seen these planted out in summer and lifted again in September. The tendency when this is done is to get the plants into large pots, and with most of us it is necessary to keep the size of the pots as small as is consistent with the health of the plants. Acoelias are valuable conservatory plants. In the old days we planted them out either as dense bushes in the borders or to cover pillars and walls, and in any situation they acquitted themselves well, but it is only in old-fashioned places that anything like a collection of Acoelias can be found now, though I think it is a pity they have been discarded, as they are among the best of the late winter and early spring flowering plants. Acoelias arvensis, Drummondii, grandis, longiflora, magnifica, and Riccartii are all good, and the last-named should be planted out in the border, and trained up under a rafter, and allowed to fall about gracefully when in bloom. There are many other species, all of which are valuable conservatory plants. They are easily raised from seeds, but cuttings make the best plants, as they are dwarfer and sturdier, and flower more freely. The Orange family are deserving of more attention.

Unheated Greenhouse.

The season is close at hand now when the flowering plants we have hitherto had in this house will fall through damp and cold. Tuberosa Begonias will go to rest. Lilies of the lanifolium section will also be ripening their growth. These will take no harm if placed in a corner where the sun shines to finish ripening. They can then be plunged in Cocoa-fibre. Early-flowering Chrysanthemums of the Mme. Desgrange section will keep the boxes gay till the autumn-flowering varieties come. For winter large clumps of Christmas Roses in variety in large pots or tubs will be charming. Veronias, such as Andersoni, and its varieties, in large bushes will last in flower a long time. These may be grown outside with the Chrysanthemums during summer. Baskets filled with variegated Ivies and Vines elegantissimas will be light and elegant suspended from the roof where there is room. For winter work large bushes of Laurestinus and Jasminum nudiflorum will be useful. American Aloes in large pots or tubs will only require the protection of a glass roof in winter, if the roots are kept fairly dry. In cold weather watering must be done with judgment and care.

Stove.

Achmeas are not so much grown as they were formerly. This is, I think, a loss, as it was an easy matter to help them on in heat in spring, and as they come into blossom move on to the conservatory, where they would remain in

* In cold or northern districts the operations referred to under "Garden Work" may be done from ten days to a fortnight later than is here indicated with equally good results.

flower for a long time; the pots could then be laid out for their sies, and the plants encouraged to go to rest for the winter. Genias, such as cinnabarin, are now becoming effective, and the early-flowering Amyrillus will soon be on the move. The Hybrid Streptocarpus are exceeding useful, and are so easily raised from seeds, which may be sown in spring, and grown on in heat. At present these are generally grown chiefly in peat, but a little turfy loam mixed with the peat will be an advantage. Peat is not nearly so much used in plant growing as it was thirty years ago. It was then thought necessary to pot all Ferns in peat, but it is now found that the majority of Ferns, both tender and hardy, will do better in loam. Ferns must be kept going regularly now, but avoid overwatering the house; 60 degs. at night is quite high enough for the average collection of stove plants. It is important that the wood of the flowering stove plants should be well ripened. This involves more ventilation and a little less water, both in the atmosphere and also at the roots. The early-started Caladiums will soon be past their best. These may be placed together in some corner, and gradually dried off. Small-growing Caladiums will not bear so much starving as will the more robust growing varieties, and the cuttings, if dried too much, will do very dry now, or at any rate the bulbs will die and rot away if they get quite dry. There are many things coming on now which require more room.

Cucumber House.

Steady progress should be the order of the day at present. Steady frost must be kept up, but the night temperatures need not exceed 55 degs, and if it does not fall below 60 degs on some will be done. I am assuming only strong plants were put out, and that they were allowed plenty of room; 6 feet for each plant to occupy will be none too much space. I would rather plant wider apart than nearer, especially for winter bearing, as they soon fill up when they get fairly into growth. Another point to be considered is never use cold water, nor yet topdress with cold soil.

Gold Frames.

Violets must have abundance of air, and just water enough to keep the roots in a nice, genial, healthy state. Tender things must be taken to warm-houses. I am thinking now of the young winter blooming stuff which are usually grown in frames in summer. Recently potted Frezias are growing freely in frames. Romes Hyacinthas are coming on. Lilies Harriet and other Lilies may be potted, covering the tubs with glass. This will give room for a little rich stuff as a top dressing when the flower-spikes are coming up. All bulbs will do well in frames for the present.

Window Gardening.

Though the season is fast abating away, the window-boxes are still very effective. A set of boxes which I often pass are filled entirely with a collection of Ivy-leaved Pelargoniums. The boxes are entirely covered with over-hanging growth, and the whole has a distinct and pretty effect. Indeed there is no lack of bloom. Scarborough Lilies, Tuberosa Begonias, and Double Zonal "Garaolum" are still in good form. Some day gas will be superseded by the electric lights, and a great impetus will be given to plant culture in rooms.

Outdoor Garden.

There is no better time than the present for planting climbers and creepers on walls, if they are kept in pots as many of them are nowadays. I was looking at a wall the other day that was planted with variegated Ivies and the Clematis "The General." The Clematis and Ivies were planted alternately, and the wall thus nearly covered the arrangement was very effective; much more so than a heterogeneous collection of plants (some of which would probably fall) would have been. It is always better in planting conspicuous walls to use well tried subjects. Ampelopsis Velutina is largely used for covering buildings, and it will in a few years reach the top of the loftiest buildings, and when well established there is no further trouble to be taken. Other useful plants are the Clematis Thorns, Escallonia Macrantha, Scarlet Trumpet Honeysuckle, and the Wisteria sinensis for lofty walls in good aspects. Among flowering shrubs suitable for covering walls are Magnolias of different kinds, Camoësa, various, and the Rose Acoelias make a charming covering for a lofty wall. One of the most elegant wall plants is the Tamarisk, and in a few years it will cover a large space. There are seen in growth now, and old plants against a wall flower very freely. The only drawback is there is nothing but bare sticks in winter, but this is the condition of many of the most beautiful flowering objects in winter. Another useful wall plant may be mentioned—viz., Berberis stenophylla. It is a charming thing at all seasons, and for north aspects the Cotoneasters are very effective. To a certain extent the Tuberosa Begonia is bound to take the place of the Pelargoniums in the flower-garden. When the colours are well selected, charming masses of scarlet, white, and yellow may be obtained with less trouble to keep through the winter than "Geraniums," and seedlings are so good now that expensive plants need not be purchased. The tubers when ripe may be packed in sand and kept in the cellar till signs of growth appear. The Dwarf Hybrid Cannes also will be useful for massing when they get cheap enough.

Fruit Garden.

Grapes in cool houses are ripening well this season, even though they are putting on the amber tint so much appreciated without much help from the sun. In the case of Muscats and Light Grapes generally all surplus growth should be removed to let in the light and sunshine to finish them off. Gros Colman wants an early start to finish it properly before the sun has lost its power. Where the Grapes have been cut attention should be given to the perfect ripening of the wood, and all young wood carrying soft foliage will be better shortened back. There is not likely to be much wood ripened this season, as the Vines are deep-rooted, and in that case set about lifting them at the first favourable opportunity. I used to think the best arrangement for Vine-borders was to have them partly inside and partly outside, but the last half dozen years' experience with inside borders has proved to my mind that with liberal feeding inside a border is the best; especially in the case of large houses. The water supply must be liberal, and there should be a hose to apply it. Fruit gathering will pay demand attention, though

the crops are heavy—too heavy, in fact. As the fruits are so small the crop in many orchards will not be a very profitable one. Vigorous young trees are bearing fine fruits, but on the old trees the fruit is only fit for cider, and this is the best course to adopt—make it into cider and keep the best fruit only for home use, or to send to market. It will be quite useless to send cheap inferior fruit this season to a distant market. The salesman's life just now is not always a happy one. Many people with no experience of marketing, and nothing beyond a small surplus to dispose of, have generally exaggerated notions about the value of things in a large market, and are difficult people to satisfy. However, all things find their level. A very useful Pear to plant for market is the Hazel. It is an easy free bearing sort, just the Pear for the coster's barrow, or to sell in large quantities, and for profit it is no use planting Pears which cannot be relied on to bear. Young Pear or Apple trees which are growing too freely may be brought into a bearing state by lifting the roots now.

Vegetable Garden.

Thin out the best Turnips as soon as large enough. Each plant should have at least a square foot to spread out a good head of foliage to shelter the bulbs in winter.

will break away will begin to strike early in spring. If the requisite temperature is kept up. Tomatoes in winter will require a temperature of 80 degs. A rich top-dressing will be beneficial now. Plant out Lettuces and Endives on warm borders or beds with a southern exposure.

E. HODDAY.

Work in the Town Garden.

Except in the warmest and most sheltered localities tender plants of all descriptions ought to be housed at once. The season has been an extraordinarily early one throughout, and it is very probable that the winter will follow suit. Even if frost keeps off for a time cold wet weather is almost equally injurious to most kinds of greenhouse plants standing outside. Here in the south, again, though the days are warm the nights are very chilly, and at the time of writing a dry and harsh wind is making everything outside look so pinched and miserable that we are getting the indoor plants housed as fast as possible. Chrysanthemums in particular are in many cases exceedingly early, and must be got under cover directly the buds show the first signs of colour, but late varieties ought to be left in the open air as long as possible. In low or damp places, where early frosts are often destructive, even if the plants

next spring. Beds for Carnations should be prepared a month, and directly the earliest layers are found to be well rooted planting may begin. Part of the stock of choice varietals should always be wintered in pots. Cuttings of bedding plants of all kinds—Calceolarias, which will do any time next month, only excepted—ought to be all in by this. Purchase the stock of Dutch and other bulbs in good time. B. C. H.

THE COMING WEEK'S WORK.

Extracts from a garden diary from September 23rd to September 30th.

Moved Zsopel Pelargoniums to greenhouse, where warmth can be given when necessary. At present they will not be hurried. For the most part they are in 8-inch pots, as I find this size most suitable. During the summer all the flower buds have been pinched off, and as a consequence the plants are now strong and in a condition to throw a lot of bloom during the winter. F. V. Raspaill is grown largely for cutting, as the flowers hang well. For producing a mass of colour during winter, West Brighton Gem, Harry Jacoby, and Master Verulam are superior to the broader petalled varietals. All my stock of bedding "Aceroliums" are still outside, and will remain so as long as they are safe from frost, and if a degree or two of frost should come, I have light covers which can be thrown over them until they can be placed inside. There is a distinct advantage in keeping them outside as long as possible, but, of course, frost must be guarded against. The beds of pelvies, especially "Paculium," Verliens, and Begonias, are still very bright, and will be left out as long as possible, everything being done by picking off dead leaves and flowers to keep them in condition. Among the plants which have been provided to fill the beds when the summer hedges have shot their belt are Tufted Panicle in several distinct colours, including blue, yellow, and white. Dianies and Primulas are also largely used with Crocus and other early flowering bulbs. Masses of the early flowering Arabis alba are valuable, because of its earliness, and comethlog will be done with golden tinted and other shrubs. I am growing a collection of Double Wallflowers in pots for spring blooming. These are now established in 3 1/2-inch pots and will be plugged in a cold frame till Christmas, when they will be shifted into 4-inch pots and placed in a light position in a house where a little fire will be used. They associate well with intermediate stocks which do well under similar treatment. Where Violet-scented flowers are valued in the conservatory in spring, these plants ought to be grown. I have reduced the growth of the strong-growing climbers in the conservatory as more light is required by the plants below, and the time is near when more flowers will be looked for in the conservatory. Early flowering Chrysanthemums are now in fine condition, especially Madame Desgrange and its varieties. When well grown, this to my mind is the most beautiful late summer Chrysanthemum. Preparations will soon be made to place some of the earliest of the autumn-flowering Chrysanthemums under cover. It is useless to keep them out after the first week in October. In cold districts it may be necessary to house those whose buds are getting prominent a few days earlier. This is the time to feed the plants growing in comparatively small pots. If sufficient nourishment is not given the leaves must go and then the blossoms will be poorly developed. Figs are wearing a good crop this year when the roots of the trees are under control. A few years ago the roots were lifted and brought nearer to the surface; a little fresh lumpy loam being added at the same time, this has been a marked advantage. Finished the removal of the Violets to frames for winter blooming. They were moved with balls and planted on the Melon beds, which had been specially prepared for the purpose, fresh soil being added to lift the plants near the glass. Busy gathering Apples and Pears. Shall not gather late keeping sorts yet. Prasad's Nonnuch and Warner's King, from young trees, are very fine. Planted Lettuces and Endives in every available warm border.

THE KITCHEN GARDEN.

TOMATOES UNDER GLASS.

FAILURES in Tomato culture are not so frequent as formerly, but sufficiently so to call in question the kind of treatment the plants very often receive. Grown in a rational manner, no fruit-bearing plant is more productive or gives better returns in a given space for the attention bestowed upon it; but, on the other hand, when in a debilitated condition, the returns are most disappointing. More often than not early Tomatoes are treated similarly to Cucumbers—that is, grown in a high and moist temperature; but the growth is so attenuated and devoid of stamina that what flowers do form fail to set. There is no danger of the plants becoming ruined through early fruiting, as the earlier fruits, if induced to form, assist in checking exuberant growth, and the succeeding blooms set better. What is needed is a strong, matured growth, built up by free exposure to sunshine with a warm, buoyant atmosphere. It is very annoying to have strong plants capable of carrying a good weight of fruit in a barren state through the blooms failing to set, and with early Tomatoes this is a very frequent occurrence. It is not during the very early stages that a warm and moist temperature is injurious, as in my case the seedlings are raised and grown on until repotted into 11-inch pots in the same structure as that devoted to Cucumbers and Melons. The only precaution taken is to keep them from becoming drawn,

Well-managed Tomatoes under glass.

though generally before severe frost comes. This bulk of the large sized usable Turnips will be lifted and stored. A good way of keeping Turnips in winter is to pull them up leaving the tops intact, digging a trench and turning the bottoms of the Turnips carefully to the trench, leaving the tops outside. Be careful in earthing up (clery not to let the soil fall over into the heart. In earthing up herbs let the earth lie loosely. The plants will not grow so freely if the soil is pressed closely against them. There is no better autumn vegetable than Yelch's Self-protecting Broccoli, the early plants of which are now just turning in; the hearts are very close and white. Three good Potatoes where quality is considered are White Beauty of Heshon, Snowdrop, and Schopmasster. This season has suited all these perfectly. French Beans in unheated frames should be covered with mats at night. Cucumbers also will require warm coverings just in case they get a little longer till the plants in the house are strong enough to bear. Watch the Tomato crop outside, and gather all the large sized fruits at the approach of frost. Small fruits may be pickled or used in some other way. Tomatoes under glass, if the plants are healthy, may be gathered through the winter. The blossoms which are not raised on the young wood will ripen in succession up till Christmas. The plants may be pruned back and the new shoots that

cannot be housed at once, they should be removed to some sheltered spot, as under a south or west wall or high fence, where a length or two of thin canvas can be arranged so as to run on wires over them on cold nights. Here they should be quite safe for another two or three weeks at least. How beautiful are the comely Chrysanthemums of the Drengre type now! The flowers are of the true Japanese formation, but not too large or marvellous, and therefore exquisite for almost any kind of decoration, cutting, &c. The original white flowered variety with its pale and deep yellow spots, G. Weimig and Mrs. Hawkins, are now well known, but some of the new Continental kinds, such as M. Gustave Guesard (rosy pink), Chev. A. Handleira (creamy-bluish), Gaston Oh. de Brailles (buff-rose with gold centre), which are in a very similar style, but of entirely new colours, should be grown as well as the older kinds. Auriculas should now be removed from the shady quarters they have occupied during the summer months and be accommodated in frames or low pits near the glass, where they will receive the full benefit of the sun, with free ventilation in mild weather. Any plants that seem to require it may be repotted now, keeping them close to the glass afterwards. If this is not done a light top-dressing of rich soil had better be given. Strongly cultivated pots of low into 3-inch or 3 1/2-inch sizes will mostly flower

which is easily prevented by exposing the seedlings to the light on a shelf near the glass. When the plants are allowed to stand pot to pot, even in a light structure, they are very apt to become much enfeebled, and the lower leaves, instead of becoming fully developed, are puny, with a very yellow cast. In most gardens the earliest fruits are produced from plants growing in pots and boxes, as these can be removed to other available places later on. In those gardens where space is limited sundry places have to be resorted to ensure their fruiting satisfactorily. I find that Early Ruby, Conference and Acquisition are admirably adapted for growing in pots and boxes, the growth not being so vigorous as in some of the other sorts. By the time the plants are potted into the 6-inch pots there is generally another structure other than the Cucumber-house in which to grow the plants, although it is advisable to allow them to remain until they have got over the shock of repotting. I place the plants on a temporary stage in one of the vineries just started. After being potted into the 6-inch pots they have become established, it will have to be decided whether they are to be grown as single stems or with two or three. The

SINGLE GORDON plants will commence to fruit the earliest, and if there is room this system may be adopted. Even with two or three shoots the method is the same. If the plants are repotted into 12-inch pots and other plants are coming on for succession, the leaders should be stopped after two or three bunches of fruit to a shoot are formed. It must not be thought that keeping the plants in the 6-inch pots is an aid to early fruiting, as in this respect they are not in the least more precocious; in fact, in the end they are behind others which have been early potted or boxed. A very dry or arid atmosphere is as much against a free set as an overmoist and close one. By keeping the atmosphere fairly moist the pollen is more potent, and sharply tapping the shoots in the middle of the day is generally sufficient. The two extremes of atmospheric conditions must be guarded against. The soil can easily be too rich and light and also loose. Where the soil is known to be poor a little kinsit and superphosphate mixed with it will greatly assist the plants; but, on the other hand, good crops may be produced with sound loam and a fourth of pulverised horse-manure. The plants delight in a firm root-run, this imparting a fruitful growth, as later on when they need assistance richer food in the form of clarified liquid will prove beneficial. In the early stages of growth Tomatoes should not receive nor do they need an overrich soil or a poverty-stricken one, both extremes proving injurious to the well-being of the plants. In conclusion, just a word of warning upon the penny-wise-and-pound-foolish plan of being niggardly with the fuel. This is not likely to happen early in the season, but to withdraw fire-heat later on will most likely result in an attack of disease. A.

4550.—**Saving Cucumber seed.**—When the fruit becomes of a yellow colour the seed will be ripe; but when it is intended to save seed from Cucumbers the plan is to fertilise the female flowers with the pollen from the male blossoms. Cucumbers will grow a full size and have no seeds in them sometimes. They may be chance fertilised, and in that case would have seeds in them; but to make sure they ought to be carefully fertilised when both the pollen and the flowers are in condition. When the fruits have been cut lay them on a shelf for a few days, and afterwards cut them open and remove the seed, wiping it with a dry cloth. When it has been laid out to dry for a few days put it aside for use in paper bags.—J. D. E.

In all probability the two Cucumbers mentioned as turning yellow contain seed; if they are swelled towards the point or "nose" they are sure to do so. Loop them up to the roof with some raffa or string, so that they lie in a horizontal position, and when they are quite ripe, which may be known by their being quite hard and sounding hollow when tapped,

cut them and lay on a warm, sunny shelf or in a window for three weeks or more. Then cut them open longitudinally, scrape out the seeds, dry them thoroughly, and store away for future use. It is better not to wash them if possible.—B. C. R.

— Sling the fruit to the wires by passing a string of melting round the end and securing it to a wire near. Cucumbers will not produce seeds unless the blossoms were fertilised. In the summer this is often done by insects, when the house has been freely ventilated. Some kinds—Telegraph, for instance—will not seed freely under any circumstances. The fruits may grow to a large size and ripen, but the

Fruiting-branches of Fig "Brown Turkey."

produce is small. The practice of sowing seeds from exhausted plants is not generally to be commended. The better way is let the plants devote their youthful energies to seed-bearing, and see that the blossoms are properly fertilised. Those who grow Cucumber-seeds for the trade generally adopt this course, and the plants from such seeds are more vigorous than the seeds from exhausted plants.—E. H.

— If the flower at the end of the fruit was not fertilised, either artificially or by insects, the chances are that it contains no seed. If the Cucumber is the same thickness all the way it has no seed inside, but should it have swollen at the extreme end into a knob-like form, that part contains seed. Allow it to hang upon the plant until quite yellow, or turning brown. The seed should then be taken out by cutting it in quarters down the middle and washed, laying them in a warm, dry place for a few days to harden.—S. P.

4560.—**Cabbage growing.**—If anyone could tell "E. J. H." how to cultivate ground for Cabbage to prevent club he would confer a boon on market gardeners and others of the greatest possible value. All sorts of "curc" have been put forward to prevent club, but none have been successful. The advocates of gas-lime have made sure that this would prevent it. I gave it an excellent chance on a piece of ground I intended to plant with Brussels Sprouts one year. The gas-lime was obtained directly from the gasworks, and a good dressing was dug in; soon after the plants were set out, and the dressing was so strong that quite three parts of the plants were killed, and the remainder were all badly clubbed. Select another piece of ground for the Cabbages, and if planted now to come in about May and June they will be free from club. There is a walk down the centre of my kitchen garden, and Cabbages planted on one side always club; on the other side they are free from it.—J. D. E.

— The soil needs lime. Give it a dressing at once, and put in a fresh lot of plants, using plenty of soot and wood-ashes or burnt soil round the roots of each. You will not be troubled much with clubbing afterwards.—B. C. R.

New Chrysanthemums.—The Chrysanthemum season, so to speak, for the present year has already opened, and doubtless readers of GARDENING, especially those in any way interested in this flower, like to know the best new things. Chrysanthemums are not like Daffodils, as they quickly become cheap, and within the reach of all who have not very long purses for plants. A very promising new Japanese variety was shown at the recent show of

the National Chrysanthemum Society, and is named Mr. E. Rowbottom. It is an English-raised seedling, like so many of our finest novelties, and belongs to the Japanese class. The flowers are self yellow, of a very delightful shade, and are attractive also for their fine form. They are not too large, as many of the later acquisitions, which are so big as to be simply coarse, monstrous blooms, fit only for the show board. Another new kind is named Samuel Barlow; the flowers, not too large, are rosy-salmon in colour, touched in the centre with yellow.—V. C.

FRUIT.

FIG-TREES IN THE OPEN AIR.

If the roots of a Fig-tree are in a suitable medium near the surface, so as to be under the influence of solar warmth, there will be some fruits. In damp situations, or where the subsoil is of a heavy nature, it will be better to keep whatever preparation is made for the roots well up from the damp subsoil. In such case I should prefer to lay down a base 6 feet square of concrete 6 inches deep. Cart a couple of loads of soil from an old pasture if obtainable, and mix with it half a load of builder's rubbish from the pulling down of old buildings, containing a large proportion of old plaster. Plant the Fig-tree on the top, with its roots from 6 inches to 9 inches from the surface. The roots, of course, would during the first dry summer make an effort to push down strong feeders over the edge of the base of the concrete, but it would be an easy matter to deal with these either in the autumn or spring. I have lifted the roots of Fig-trees at both seasons with about equal results, and with an impenetrable base 6 feet square beneath them, the roots, passing over the edge of the concrete, would be none the worse for an annual lift up. When the roots are kept near the surface, and the young

WOOD PROPERLY THINNED in summer, so that it may become hard and firm, there is not much danger to be apprehended from the frosts of an average winter. Still, unlike most other fruit-trees, the Fig is not injured by being thickly covered in winter, and, to make sure, it is generally advisable to cover the branches towards Christmas, as there is never any frost severe enough to injure the wood of Fig-trees before the middle of December. There are various ways of affording protection; perhaps the simplest is to uncoil the braiches, draw them together, and cover with Spruce or Yew branches. Dry Bracken will do as well, so will straw, or mats may be nailed over them. No great thickness of anything is required, and, as I have already said, in ordinary seasons no covering will be wanted; it is only to meet the severe winters which visit us at more or less lengthy intervals that I should cover at all. The best all-round kind for the open air with which I am acquainted is the Brown Turkey. Fruiting branches of which are here figured. I am told there are many varieties of Figs grown in Italy and in other Fig-growing countries that would be worth a trial here, and there is the possibility of something being done by raising seedlings, but Figs are queer things by hybrids. Still, there is hope for the raising of seedling Figs, as we are not yet overburdened with really good Figs suitable for open-air culture. Under fairly good management there never need be a failure of the Fig crop, as the young fruits do not start into growth until the weather is settled, and the blossoming period comes a good deal later. E.

4547.—**Thrips on Vines.**—These are very troublesome, and when they have become well established on the Vines it is difficult to remove them. Strong fumigation with Tobacco-smoke may destroy them, but this might give the ripe Grapes an unpleasant flavour, as the thrips can seldom be destroyed unless the house is fumigated twice, or even three times. Painting the pipes with flowers of sulphur when they are well heated is an effective agent of destruction; it kills red-spider as well. I have not seen any thrips on the Vines since I used the sulphur fumigating.—J. D. E.

— Fumigating the Vines with Tobacco-smoke on three successive nights will generally rid the Vines of this pest. It will be a good plan, however, to repeat the dose in about a

fortnight. The smoke will not hurt the Vines or the fruit; the smell will pass off in a few days if air is liberally admitted to the vinery. If the Fuchsias are in pots stand them out-of-doors for six weeks, letting the plants have a touch of frost. If they are planted out in the vinery, syring the leaves with soft-soap and Tobacco-water, not too strong.—S. P.

4538.—**Bottling Grapes.**—What is meant by bottling these is quite different to bottling stone fruits. Ordinary wine-bottles are filled with water and tied to a rail loosely; the bottom of the bottles rest upon a ledge, and are tipped over to an angle of about 45 degs. The bunches of Grapes are cut with the lateral branches attached to them. Insert the end of the bunch in the bottle of water, and the bottles being at the above angle will allow the bunches to hang clear. I have kept bunches of Lady Downes' Seedling Grape in good condition in this way from Christmas until May. All my Grapes not cut by the first week in January are preserved in bottles. The bunches take up a good deal of water, which has to be renewed once a week.—J. D. E.

—The bunches of Grapes are cut with enough of the wood on which they have grown to reach down the bottle for the Grapes to hang clear. It does not make much difference which end of the shoot is thrust in the water, as water will be imbibed from either end. Any room may be fitted up with shelves or racks for placing the bottles upon in a slanting position. All that is required is an equable temperature of 45 degs. to 50 degs. Grapes under such conditions will generally keep longer than if left on the Vines.—E. H.

4563.—**Management of Pear-tree.**—It is possible that root-pruning might bring the trees into a fruitful state, but I have my doubts about it. I have had no good results from regrafting unfruitful trees with other sorts that this is a case in which I should adopt the same plan in preference to any other, as I believe the secret of the barren state of the trees in question is that the position does not suit the sorts. If you are fond of experiments you may regraft two of the trees and root-prune the others.—J. G. C.

—Your question is really too meagre to tell what is required. You give no particulars whatever, and I should think that as other things in the garden seem to be satisfactory, that you have got varieties naturally shy bearing. Some kinds give comparatively few fruits, although the trees may be in the best of health, and received proper treatment. Send samples of the fruit, or say whether the trees seem to require pruning at the root through overluxuriance in growth.—C. T.

—The trees probably require root-pruning, if they are making much wood. The old aphorism "He who plants Pear-trees for his heirs" need not be true if the roots were kept under control. If you could get a practical man to look at them he would tell you what is best to be done, but the probability is that lifting or shortening the roots will have the desired effect.—E. H.

4500.—**Vines in a cool house.**—Notwithstanding that very good Grapes can be grown in pots, it is much more satisfactory to have them planted out in a border, either in a cool or unheated house. In pots they only last one season, whereas planted, the canes should be in good condition thirty years hence. It is not necessary to make a large border for Vines at once; in fact, it is a much better plan to make it piecemeal—say begin with a border 3 feet wide and add 2 feet to it yearly until the space is filled up. It is a matter of convenience whether the border is wholly an inside one or not. Good Grapes can be grown with the roots outside entirely, but from choice I prefer to have them inside the house, where they are more under control. The worst evil in Vine-border-making is that of having it too deep; 9 inches of drainage at the bottom, and 2 feet 6 inches depth of soil is quite sufficient for any variety. Freshly cut turfy loam is the best material for Vines to grow in when mixed with charcoal or old lime rubble, adding a small quantity of wood-ashes for the purpose of providing potash for the Vines. Farmyard manure should never be added to the soil when making a new border. If loam or freshly cut turf is not available, a wet garden soil will answer very well, providing a little of Thomson's or Innes' Vine-manure can be added along with the charcoal, wood-ashes, and half-inch bones. When the border is added to yearly

fresh soil is given to the roots to run in—this is what they like. A retaining wall of turf can be built annually to keep up the loose soil; in this the roots will be quickly found showing what they like. As to the best varieties to grow, Black Hamburg and Alicanto are the most suitable of that colour for an unheated house, and Foster's Seedling if a white kind is required. One-year-old canes are the best for planting, but for fruiting in pots two-year-old canes are the best. Those that have been cut down once are the strongest, producing fruit the same year. Pots 12 inches in diameter are not too large for Vines to fruit in.—S. P.

FRUIT-TREES AS ORNAMENTAL SUBJECTS.

Why should not fruit-trees be grown more for their beauty when in bloom? When we consider the flowering charms of a great portion of our fruit-trees is it not surprising that they are not more grown for their beauty when in flower? In early spring nearly all hardy fruit-trees, such as Apricots, Peaches, Plums, Cherries, Almonds, Apples, and Pears, are more or less ornamental—the double-flowering Peach, Cherry, and Almond being particularly so. All of these trees should be planted more abundantly than they are, for in the spring no shrubs are more attractive. They may be grown in any form, bush, pyramid, or standard, and to various sizes; and when flowering as standards in the open borders they form conspicuous objects. A little attention, however, is required as regards keeping them well supplied with young wood, as upon this the flowers are produced. They should also be planted in good soil to induce them to make plenty of growth. The double-flowering varieties of the Peach, Cherry, and Almond also force well. They are of easy cultivation, and well deserve a place in the conservatory amongst other flowering plants. When grown for this purpose they should have the same care in cultivation as when grown for fruit. Young maiden plants may be obtained from the nursery; these should be potted in the autumn and placed in a cool house until required for forcing, when they should be removed to a warm house, where they will soon flower, after which they should be placed in the cooler quarters, where they will continue in bloom for a long time. After flowering the plants should not be placed outside all at once, as is the

open space in pleasure grounds or by the side of woodland walks, instead of the worthless subjects which now too often occupy such places. B.

4539.—**Treatment of Nut-tree.**—Filberts and the ordinary Cob-nuts are very easily grown. It is better not to prune them any further than merely to cut out any crowded growths, or such as would cause the trees to get out of shape. Nearly all the varieties of them have a tendency to throw suckers from the bottom of the trees, and they will continue to do this until quite a thicket of growth is produced; if this was allowed to continue, the suckers would take the sap intended for the trees, and prevent their assuming a shapely head of fruitful branches.—J. D. E.

—When a Nut-tree has been started right at the beginning there is not much difficulty in keeping it right, but old bushes which have been allowed to run wild from the first had better be thinned, only without much attempt at shortening. A young Nut-bush should be worked on the model of a well-managed Gooseberry, with an open centre and low wide-spreading branches, thinned moderately. The object of the pruner should be to fill the bush with feathery spray.—E. H.

—Presuming young trees are obtained from the nursery with from three to six shoots on a stem 2 feet long, they should be planted 8 feet apart in any open position in well dug soil, but not too heavily manured. Directly the leaves have fallen is the best time to plant. In February following the shoots should be cut back to within 4 inches of the base to induce them to push strong shoots. The next year the leader should be cut back to within 1 foot. The trees should be shaped so as to have about ten main branches to each. The side growths should be spurred in after the manner of Vines, as from these spurs the nuts are obtained in quantity. The centre of the tree should be kept open to admit of sunlight and air freely.—S. P.

4541.—**Fowl manure.**—This is suitable for all, or very nearly all, kinds of plants, but, being of a very strong and burning nature, it should be either given in a liquid form, steeping, say, a peck in a large cask or tub of water, stirring well, and then allowing it to settle before use, or else be mixed with five or six

Flowering-spray of Pear "Citron des Carmes."

usual practice with subjects that have been forced; they should be kept under glass and well attended to in the way of watering and keeping free from red-spider, aphid, &c., until the summer, when they may be gradually hardened off and finally placed out-of-doors in a position where they can have the full rays of the sun, so as to thoroughly ripen their wood. The common wild Cherry is very attractive when in flower. The wild Crab is also very attractive. Many trees of this sort would be well worth the trouble if planted in any

times its bulk of fine sandy soil, and the whole allowed to lie in a heap for a short time.—B. C. R.

4552.—**Snails in a garden.**—The only way of dealing with snails is to catch them, and they must be looked for early in the morning or in the evening, just as for slugs or caterpillars, which must be diligently sought for to get rid of them. If there is any particular wall which they climb, make a preparation of train-oil and soap, which if daubed along the bottom will prove a very good barrier.—C. T.

TREES & SHRUBS.

JUDAS-TREE (CERCIS SILIQUASTRUM).

This (leaves of which are here figured) is certainly not so often met with as it ought to be, and yet few ornamental trees are really more successful. In the South of England it will also succeed as a single specimen on the lawn, where it often assumes the proportions of a tree. In more northern districts it is deserving of a wall.

4536. — Evergreen creepers. — I am afraid you will have to include also some things that are not evergreen, if you wish for a good assortment. The majority of the most beautiful hardy climbing flowering plants are deciduous, but a few you may get, such as Magnolia grandiflora, which will be some time, however, before it gets to any size, and the Fiery Thorn, or Pyracantha, which is a very handsome flower.

In the earlier part of the year it blooms in profusion, and the clusters of white flowers are remarkably attractive, but in winter the plant is brilliant with orange-scarlet berries, which cluster thickly on the shoots, and are in rich contrast to the deep-green luxuriant foliage. Of course, such a plant will take far longer to cover the wall than the deciduous climbers. I give the names of a few deciduous kinds, such as Clematis montana, which is one of the best of all climbers, if you can keep it fixed well to the wall. I know a house absolutely covered with it, festooning about the windows, and in the month of May it is very charming with its lovely white fragrant flowers. It is a very hardy species, and will grow in ordinary soil. Then you may have Veitch's Virginian Creeper, which clings tightly to a wall, and grows very quickly. The colour of the foliage in autumn are very beautiful—gold, crimson, and allied tints. The winter-flowering Jasminum nudiflorum is a very pleasing kind, producing on its naked shoots in winter a profusion of yellow flowers, which give a glow of colour to the garden at a time when it is most needed. Against the wall a good plant of the double-flowered Kerria would make a show, as the flowers are produced very freely early in spring. Roses, such as (Fleure de Dijon), would succeed well, and there is no finer Rose for an ordinary garden. It grows strongly, and is a perfect sheet of fragrant flowers in the summer months, and is not afraid to produce a few blooms in the autumn. The Wisteria sinensis is worthy of note, but this is also deciduous. All the things named will thrive in ordinary soil, and give no trouble. There are a number of things that might be recommended, but they are not really hardy, and likely to prove a nuisance than otherwise. You might get—but again the plant is deciduous—Chimonanthus fragrans, which blooms in the winter, and a good specimen will prove welcome, as the flowers are very fragrant, quite a rich spring fragrance, and of a rather dull yellow colour with brownish sepals.—C. T.

It would have been an advantage if "John" had mentioned his locality. If he resides in the south, Magnolia grandiflora (Exmouth variety) is a grand wall plant. It is rather slow in starting, but when 20 feet or 30 feet high it will be worth looking at. Escallonia macrantha, Ceanothus dentalis, C. Veitchi, Crataegus pyracantha. There are two varieties of this evergreen Thorn, the difference being in the colour of the berries; but I think the scarlet-berried sort is the most effective, but this is a matter of taste, and where winter effect is sought it might be advisable to plant both. Lardizabala hitornata is a very handsome evergreen wall shrub. When first introduced it was thought to be tender, but it has proved itself hardy. It should be understood that things

which will prove permanent are often at the beginning of slow growth, but the plants named will give character to any building, and are worth waiting for. Have the site trenched up 2 feet deep, and any bad soil removed. If the soil is poor, manure liberally.—E. H.

— The White Jasmine (J. officinale) and the yellow (summer-flowering) variety (J. rotundum), and though not evergreen, the winter-flowering J. nudiflorum would make a nice addition; Escallonia macrantha, Garrya elliptica, Osteospermum chlorophylla, and C. Simondsii, Magnolia grandiflora, and M. Ericoides, and the Evergreen Rose (R. sempervirens).—B. C. R.

4512. — Planting Clematis. — The best Clematis for a north-east position is the beautiful white-flowered variety, C. montana. It is doubtful whether any of the other kinds would

Leaves of Judas-tree (Cercis siliquastrum).

do much in so cold a spot, but C. Jackmani, with masses of purple blossoms, might be tried. The end of February or beginning of March will be a safer time than the present to plant a young Clematis. If, however, a well-established plant of two years' old can be procured as once and well planted, mulching the surface afterwards with fresh manure, it might do well, and would start earlier than if spring-planted. Should severe weather set in, however, it would be best to mat it up, for plants which have not yet had time to get a thorough hold of the soil are much more liable to be destroyed by frost, followed by bitterly cold winds. The answer to this query depends so much upon locality, and also the amount of shelter which the north-east front of the house may have from other buildings, that it is difficult without information on these points to pronounce a definite opinion.—I. L. R.

4540. — Clematises. — These Clematises which produce the largest flowers are not the freest bloomers. The magnifolia section produce large flowers, but the Jackmani type are the freest bloomers. At the present time there are more of Clematis Jackmani sold than any other, and the variety of Jackmani called Snow White is a good companion to it. Henryi is also a good white, larger than Snow White. Countess of Lovelace (double lilac), Duchess of Edinburgh (double white) belong to the Florida section; the flowers are large and handsome.—E. H.

You ask a question that entails a somewhat lengthy answer. Many Clematises, although having beautiful flowers, grow weakly, and are not, therefore, of great value for the garden. The Clematises represent a large family, and are divided into different sections. First, we have the patens type, and varieties bloom in the spring form, it must be remembered, the old wood, so if you ruthlessly hack the shoots about you will cut away the flowers. Three very beautiful varieties of this section are Fair Rosamond (blush-white), Lady Londesborough (silvery-white colour), and Miss Bateman (white), of the Jackmani type. You must not secure C. Jackmani, which has very rich dark-purple flowers, produced very freely. It is one of the best of all Clematises for the

garden. C. Fiammola is worthy of note for its profusion of small white fragrant flowers. O. rubella (rich purple) is a good kind. Of the viticella type, very pleasing are the varieties Mrs. James Estoman (light lavender) and venose (purplish-red), a very fine thing. C. montana will quickly clothe a house, as it is very free, and does not seem to care about position, the flowers being produced in the month of May. It is very hardy, grows in ordinary soil, and blooms profusely. There is a class of Clematises that does not climb at all, such as C. erecta, which is of erect habit. If, however, you require only a few kinds, limit yourself to those named, commencing first with the free and richly-coloured C. Jackmani.—C. T.

4542. — Raising Quick. — This query is a good illustration of the impatience of the present time. This is not a waiting age; but in the matter of raising Thorn Quicks there must be a considerable lapse between the sowing of the seeds and the setting out of the plants. But when strong Quicks, suitable for planting, can be bought for three or four shillings a hundred, why wait for seedlings? It will, under the most favourable circumstances, take several years to get Thorn Quicks large enough to set out, and most people find it better to leave this work in the hands of the specialist. Haws are generally kept twelve months pecked away in a heap of sand to remove or soften the coverings of the seeds. If planted as soon as ripe the seeds would not grow the first year, and it is found better to mix them with the sand in a heap for twelve months before sowing.—E. H.

The haws when gathered should be thrown into a heap, and covered with soil to get rid of their outer covering. The following April they would be ready in sowing broadcast in well-prepared soil, not too thick, covering the seed with fine sandy soil. Here the seedlings should remain for eleven months, planting them out afterwards in rows, 10 inches apart, the plants 3 inches in the rows.—S. P.

4541. — Removing old tree-stumps. — There is no better way of removing old decayed tree-stumps than digging round them, and grubbing them out. A good workman will soon clear a piece of ground. This is work in which experience is of greater use than grubbing or falling timber. It always saves labour to clear a good piece round the stump, so as to get well under it before beginning to cut.—E. H.

4558. — Evergreen hedge. — The broad-leaved Evergreen Privet makes a capital hedge, and it will grow in front of trees as well as anything; but the best of all evergreen hedges is the common Holly. When it has once made a good start it grows as freely as the Privet, and will form a very high hedge, which the Privet will not. Some persons would choose the Privet because it grows a little more quickly at first; but I would unhesitatingly select the Holly as making by far the best hedge in the end. Arborvitae and some of the Cypress family have been used as hedges, and in some soils do well; but I would place Privet and Holly before them.—J. D. E.

Nothing grows quicker than Privet, and if the evergreen sort is planted it will make a good blind all the year round. If the fence is required to keep cattle back the Privet alone is not firm enough; a Quick planted every yard strengthens the hedge considerably. Holly is perhaps the best of all evergreen hedges, but it is slow growth. Whatever is chosen, the main point to observe is to prepare the site thoroughly by trenching the soil 18 inches deep and using manure freely, both in the soil and as a mulching.—S. P.

Privet would do well for the summer, but in severe winters it frequently loses its leaves. Laurel would be far better, and is quick growing, but the much slower growing Holly would make the best hedge of the three.—A. G. BURTON.

Nothing better, if time is an object, than the Evergreen Privet. Otherwise a Holly-hedge is superior to anything else of its kind, but it takes a good many years to attain a fair size.—B. C. R.

The common Privet makes a good hedge quicker than most others, and if a few Thorns or a few Myrobala Plum are planted with the Privet they will help to strengthen the hedge.—E. H.

4511. — Clematis Jackmani. — The end of October or beginning of November is a good time to purchase and plant out this Clematis or any other. The plant would not be large, and no pruning is necessary the first year or any year. I allow the plants to grow freely as they like. If they are trained to a wall all they grow to are allowed to remain, and they hang out, after a time, as much as a foot or two

OUTDOOR PLANTS.

WILD GARDENING.

AMONGST the numerous species of strong and hardy herbaceous plants that are suitable for naturalising in woods or other semi-wild places, the following are a few that have been found to thrive well, regardless of rabbits or the encroachment of rank and wild vegetation. The plan adopted in some cases has been (and I think it is the best one) to plant bold colonies of distinct species in separate groups, while in others a mixture of herbaceous and bulbous plants has been tried, whilst a single specimen of such a rampant grower as *Polygonum cuspidatum* is quite effective enough in itself; it succeeds in almost any kind of soil or situation, and after planting out a single plant it will in a few seasons develop into a large, spreading bush, and when in full bloom is highly ornamental. Perhaps it is seen to best advantage and is most effective on a Grassy bank or rocky steep; it is infinitely more at home and beautiful in such a site than when crammed into a formal herbaceous border, where this truly wild ornamental plant may too often be seen kept a prisoner and restricted in growth by a constant application of the spade about its roots, instead of allowing its stoloniferous habit of growth unlimited freedom to ramify at its will.

BOCCONIA CORDATA (here figured) is a vigorous grower, but does not succeed so well on thin, poor ground as the *Polygonum*; it seems to prefer a deep and fairly good soil. It is a plant well worth the trouble of preparing a place for its reception by means of turning and enriching the soil. When seen in vigorous growth its tall stalks of large, uncommon, and curiously out-leaved of a peculiar hue render it an exceedingly attractive and conspicuous plant amongst native vegetation. The different sorts of Comfrey, although strong growing subjects, are suitable plants for distributing on the sides of wood rides

allowing them ample room to increase in size every time they are cut down after blooming. When forming these groups I have in some cases filled up the bare spaces between the plants with *Pulmonaria* (common Lungwort), so as to get the ground quickly covered, which I think answers better than waiting until covered by natural herbage, as rabbits are so mischievous wherever soil is exposed on the surface; and, moreover, the *Pulmonaria's* spotted leaves and pinkish-blue flowers produced in early spring are doubly welcome at that season. If the groups appear to the eye somewhat stiff in outline, which newly formed clumps invariably do, in spite of care, to give a natural appearance at once a few stragg roots of Ferns are dropped in here and there, as it were, at various and irregular distances from the Comfrey, a plan I think worth doing, as the Ferns give an easy and more natural finish to a group than any other plants I have tried. Monkshood (*Aconitum tauricum*) has succeeded well in the woodlands; although not so robust as the preceding ones to fight against rough growing neighbours, it will, however, if liberally treated by giving it a good start in rich soil, be easy to establish in colonies where its dark-blue flower-spikes pushed up into prominent view at this season of the year cannot escape notice. Of course the rabbits do not deign to taste its poisonous juices; it therefore may be freely planted where rabbits—the worst enemies we have in the case of wild gardening—are plentiful.

WHITE FOXGLOVES and improved varieties of the common wild plant are very desirable additions to the wild garden; a group of the white variety of from a dozen to a score of plants growing near the stem of an Oak-tree a little distance from one of the principal rides in the ornamental woods is just now a pretty sight—not a bold, staring, conspicuous-looking colony, but half hid by surrounding subjects. Right in front of the group is a spreading bush, and on either side of the Foxgloves end close to them are some strong vigorous herby Ferns, their fresh green fronds half hiding the tall stalks of the Foxgloves, and giving a soft and refreshing contrast to the erect group of pure white flower spikes. The beauty of a group of flowers may, I think, be much enhanced by its surroundings; in this case the grey Lichen-covered stem of the hurlly Oak and the Ferns, etc., lend a soft and modest look to the smart, showy Foxgloves. A good sight had obliquely in passing either way is, to my thinking, more pleasing to the eye than when fully exposed to the gaze on every side, and in the semi-shade of the Oak-tree the pure whiteness of the Foxgloves and the refreshing greenness of the Ferns seems more strikingly intensified.

MULGEDIUM FLUMERI, a big hardy plant with huge leaves, doubtless flourishes best in a deep, rich, light soil; single specimens of it having been cut in the woods about three or four years, I can vouch that it can be planted in the rougher parts of a wild garden and left to take care of itself, as nothing seems to interfere with its rapid and vigorous growth. As an isolated plant on Grass it presents a bold and uncommon appearance, and when growing among other plants its remarkable leafage forms a strong contrast, and at once arrests observation; its fine and comparatively small flowers are not particularly attractive.

THE *CAMPANELLA LATIFOLIA* is one of the best of the species for the fringes of wood rides and drives. Only given a fair start in well stirred ground with the addition of some light rich soil, and it will soon develop into compact, vigorous, showy clumps, throwing up strong grass stalks laden with flowers. Too well known to need description, suffice it to say that no wild garden should be without this *Campanula*; there are many other varieties varying from 6 inches to 3 feet high, all desirable flowers for naturalising in woods and plantations; the dwarfier kinds of course, should only be planted on rockeries

from the wall, the shoots hanging loosely and smothered with flowers. If the plant gets beyond bounds the shoots must be cut in before growth begins in the spring. The same remark applies if the plants are trained to a wire trellis. Avoid always formal close cropping.—J. D. E.

You can plant in the autumn or during early spring, or either season will suffice. The soil must be moderately rich, and secure good plants in the first instance. Let the shoots alone. Amateur gardeners are fond of hacking with the knife, and thus spoiling many beautiful things through this bold surgery.—C. T.

4557.—**Tobacco.**—I do not think home-grown Tobacco will kill the smoker or I should not have been alive now, but no smoker who knows what good Tobacco is would smoke it. Tobacco grown in this country is not of good quality, no matter how it is manipulated. Years ago I used to grow it for fumigating purposes, and after the leaves were dried they were tied in bundles, placed in a heap, and covered with mats to induce fermentation. When this had set in, they were partially dried and then tormented again. Afterwards they were dried and packed in boxes and stored away in a dry place for use. I have made cigars of the best leaves. I used to smoke them, but the memory of those smokes is not exactly pleasant. It should be understood that Tobacco grown in this country is liable to the same duty as the imported article if grown in sufficient quantity to be of any use.—E. H.

4548.—**Bedding "Geraniums."**—The Zonal you mention are all good. To these you may add *Veevrius*, C. V. Raspail, Sam Jacoby, Aurora borealis, and Gloire Lyonnaise, New Guinea, Anrea perfecta, Omphale, Kate Greenaway, Queen Matilda, Queen of the Belgians, Queen of the Whites (improved), Harry Hoover, Master Christine, Mrs. Deane, Magenta King, Blushing Bride, Crystal Palace Gem, Mrs. Pollock, Happy Thought, Freak of Nature, Her Majesty, and King of the Bronze.—A. O. BUTLER.

Henry Jacoby (deep crimson) and John Gibbons (brilliant scarlet) are two of the best bedding varieties in cultivation; Ed. Sutton I do not know. Other excellent varieties for this purpose are the old *Veevrius* and West Brighton Gem (scarlet), M. Myriel (orange), Beckwith's Pink and Mrs. Turner (pink), and Eureka and Niphotes (white). A really good salmon-coloured Zonal for bedding is still wanted.—B. C. R.

The varieties mentioned, except Ed. Sutton, which I do not know, are useful for bedding, and the best for the purpose is the popular Henry Jacoby, which is the finest of all bedders and grown more largely than any other kind. The plant is of strong growth, and the flower-heads large, whilst the colour is intense crimson. It is in every respect a good kind, and also fine in pots, for which it is grown largely.—C. T.

The names mentioned are all good. In addition to these may be mentioned Master *Veevrius* (scarlet), larger and better than the type; West Brighton Gem, very free and effective (scarlet); Mrs. Mules (pink); Lucas (rose); and Queen of Whites.—E. H.

4507.—**Treatment of Lilacs.**—I should certainly recommend you to plant out in the autumn, putting a good handful of silver sand under each bulb, and covering with about 6 inches of rich light soil. If you leave the bulbs in their pots until spring, they will be turning fresh roots, which will be liable to injury during the process of planting out.—A. O. BUTLER.

4509.—**Cuttings of "Geraniums" and Pansies.**—August is the best month in which to put in cuttings of the above, and both of them strike best out-of-doors, the "Geraniums" in the sun and the Pansies in the shade. I strike both of them in light sandy soil; the "Geraniums" in boxes so that they may be removed to a heated house for the winter. Gooseberries and Box can both be propagated freely from cuttings. The Box should be planted in a shady place at once, taking cuttings of the young wood 4 inches to 6 inches in length. The Box used for edging is propagated by division. November is a good month in which to plant Gooseberry cuttings.—J. D. E.

There is no time to be lost now in taking cuttings of "Geraniums." They will want a little warmth to complete the rooting in October. Pansies will strike freely now in a cold frame, either in pots or in a bed of soil covered with glass, a handlight will do. Cuttings of Box will root now in a shady border, and Gooseberry cuttings as soon as the leaves fall. Select the best and straightest young shoots. They should be at least a foot long.—E. H.

OUR READERS' ILLUSTRATIONS: *Bocconia cordata*. Engraved for GARDENING ILLUSTRATED from a photograph sent by Mrs M. Gurney, Thelkthorn, Hethersett, Norwich.

or other rough spots, and a very pretty contrast they give at a little distance when exhibiting their drooping flowers of many colours, obtained by planting groups of different kinds together of half-a-dozen or more plants, composed of the white, blue, and purple varieties, with a plant or two of *Anemone italica* amongst them, this being a natural relation of the Comfrey. They are planted in an informal group, some rather close together, others 3 feet or more apart, thus

or other places clear of rough and tall vegetation.

THE SPIRÆA, or Meadow Sweet, is quite at home in the woods on the sides of lakes and ponds. *S. Aruncus* and *S. Gmelini* are just now in full bloom; their numerous white plumes waving to and fro in an exposed open glade of the woods are conspicuous ornaments at a great distance off, and even when under close inspection they are none the less graceful and beautiful. The rosy broad corymbs of *S. venusta* form a fine contrast to the white varieties. It is, however, hardly so vigorous a grower, and should be planted in strong clumps or roots, and where it is not likely to be overgrown by rougher plants. These Spiræas are great feeders, and thrive best in deep, rich, moist soils. If the situation is dry and inclined to poverty, a mulching of manure in autumn is of great service until they become thoroughly established in their permanent quarters; indeed, small woody plants of any kind should not be used for wild garden planting, but should be grown on in a nursery or trial ground for several years preparatory to planting out in rough places.

HEMEROCALLIS DISTICHA AND FLAVA are a success in woods; solitary plants of the former variety underneath old Thorn bushes where herbage is short and bare thrive wonderfully well, and rabbits do not seem to interfere with them. *H. flava* is planted in a colony, with the Poet's Narcissus between. Being a very prominent site, it was thought desirable to decorate it with flowers as long as possible. The bloom of the *Hemeroallis* quickly succeeds that of the Narcissus, and keeps up a succession of flowers well nigh through the summer. The *Hemeroallis* does well in almost any kind of soil; even in a wet site on a heavy clay a clump of *H. disticha* flourishes and increases in size yearly.

THE BROAD-LEAVED SANFRAGE, with pinkish flowers, is an excellent plant for the wild garden. It has been growing in the woods about four years underneath an old Thorn-tree, and blooms beautifully; nothing appears to molest it or check its development. It is one of the best of the prominent class of plants for woods or wild gardens. The broad, glossy leaves and spikes of pinkish flowers are distinct and pretty, and contrast strongly amongst native plants.

IRIS (SPANISH OR NARROW-LEAVED).—A blue variety of this has been tried in the woods here with partial success. Where planted in bare ground rabbits have nibbled and more or less damaged many of them, but where the herbage was moderately strong they have grown on and multiplied. When scattered about indiscriminately in small groups in a green glade, they are both natural looking and effective. The kind to which I allude is a dark blue variety with a white eye in the centre of the falls, a very common sort in cottage gardens about here. It grows freely in almost any kind of soil and increases rapidly when once established. Doubtless the majority of the Iris family, both broad and narrow-leaved, are most desirable plants for the wild garden, either for planting on Grass or for decorating the fringe of a lake or pond. Judging from the appearance of a collection of Irises in the trial ground in our nursery, each having formed strong roots, one can form some idea of the beautiful effect which they will present when transferred to grassy glades or other wild and suitable spots.

OMPHALODES VERNA has been established several years in various sites alongside the wood ride. Although it grows well enough and soon spreads about where the Grass or herbage is not too rank or strong, I have found that it will not flower freely unless it is planted in a warm corner and fully exposed to the sun; indeed, if the position be a shady one no flowers appear. Near one of the wood rides there is a good mass of this sprouting, intermixed with *Camassia esculenta*, which is well shown off on a sparkling blue carpet of flowers in spring, and no sooner have the charmingly Forget-me-not-like flowers of the *Omphalodes* passed away than they are succeeded by the none less beautiful blue star-shaped spikes of the *Camassia*. After the latter has done blooming, and its foliage has withered, the *Omphalodes* forms a secure sheltering rug for the bulbs, keeping them secure from all enemies and out of danger way. The *Omphalodes* should be planted where the natural growth is not too strong, and if the

ground be thin and poor, a top-dressing of rich light soil spread thinly over all in the autumn will be very beneficial, as the *Omphalodes*, after extracting the goodness out of the soil, is inclined to wander off in search of fresh food, and will attempt to establish a new colony elsewhere; in the woods, however, the rank growth of weeds very often prevents too much for it, and eventually it loses itself amongst strong growing natives.

G. B.

4505. — **Manuring ground.**—In my opinion it is not wise to dig into the ground artificial manure of any kind, for the reason that all these stimulants are quick in their action, and their worth would be wasted if applied in the autumn. The best plan of preparing the ground for any kind of vegetable crop is to trench it 2 feet deep in the autumn, keeping the surface soil in the same position, and returning that from the bottom of the trench to the same place again. If the soil is heavy and retentive a layer of long straw manure, wood ashes, old potting soil, or decayed vegetable refuse, laid between the top and the bottom spit of soil, will do an immense good, rendering the whole in a better working condition. Trenching should be done as early in the autumn as possible to admit of the full winter's frost to act upon the soil and to allow it time to settle down before the spring crops are put in. It all depends upon the kind of crop to be grown what sort of manure should be recommended and how applied. In the case of Potatoes superphosphate of lime and kainit, two parts of the former to one of the latter, sprinkled in the rows at planting time is an excellent stimulant. In the case of any of the Brassica tribe a teaspoonful of nitrate of soda sprinkled on the soil about the stem when partly grown, choosing a showery time, is good. For Carrots, Parsnips, and other roots a very small quantity of dissolved bones mixed with wood ashes at the time of sowing the seed will suffice.—S. P.

4513. — **Neapolitan Violets.**—The month of April, or not later than the beginning of May (in a backward position or season), is the right time to make a Violet-bed, though strong roots may be removed in the autumn (October), and will flower well the following spring. It is best, however, to start with the single runners, or crowns, planting them in the spring in a sheltered but sunny bed of loamy soil that has been well dug and manured. Plant the runners 6 inches or 10 inches apart, with a little more space—say 12 inches—between the rows, and keep them well watered in dry or hot weather. The runners should also be removed as fast as they are formed, as in dealing with Strawberry plants. There is only one kind of Neapolitan Violet—viz., the double lavender purple, with white eye. This and Marie Louise are still two of the very best in cultivation, though *De Parme* (purple), the *Swanley White* (syn. *Comte Brazza*), and *Belle de Chateaux* (white) are also well worth a place.—B. C. R.

— Marie Louise and De Parme are the best double Blue Violets; *Comte de Brazza* the finest white. If well established roots can be procured any time this month, and planted in rather sandy soil in a cold frame, abundance of bloom should be obtained from the middle of October until the same time in March. Without the plants have been prepared specially for winter-flowering it is useless to expect a full crop of flowers. By removing the runners during the summer the whole energy of the plant is concentrated in the maturation and development of the crowns. Some persons say that bottom-heat is necessary to give good results, but this is a mistake. Place an ordinary cold frame in a sunny position, where it will be out of north or east winds; a 3-inch thickness of soil is sufficient for the plants to grow in, the remainder of the frame underneath should be filled up with faggots or clinkers; anything to provide ample drainage, and to raise the plants close to the glass. In planting, the leaves of one plant may just touch those of its neighbour. Give a thorough soaking of clear water to settle the soil about the roots. The lights need not be put over the plants until there is danger of frost injuring the leaves. The sides of the frame should be protected from frost with manure or freshly-gathered leaves; double mats will do the same thing on the glass. Abundance of air

during the winter when the thermometer out-of-doors registers a few degrees above freezing, will be an advantage in keeping the plants stocky and free from damping of the leaves. Water will seldom be required. Thoroughly examine the soil a few inches deep before applying any water; then if necessary give a good soaking in preference to dribbles.—S. P.

4545. — **A fine Sunflower.**—Your question loses in interest because you have not indicated the kind, whether an annual or one of the perennial species, which are often very tall. If an annual, then the height is unusual—7 feet or 8 feet even being one of the common. But such perennial species as *Helianthus giganteus* will grow even 10 feet high, producing slender shoots which wave about in the wind, with delightful flowers, exquisitely graceful, and free. They are very different to the ordinary annual kinds, having small yellow flowers comparatively, but they literally smother the shoots.—C. T.

ORCHIDS.

LÆLIA PERRINI.

FROM "James Elliott" comes some flowers of this plant; but they are so thin and had in colour that I feel constrained to say something about the species in order to assist him and others in having this plant at its very best. When, of course, if the plant or plants do come of a had colour I should advise them to be destroyed, for there is plenty of it in the country, and of good form, so that the bad ones should be stamped out. It is a plant that has been known in our gardens for upwards of sixty years, and I do not think it has ever been lost since, and it has not appeared to vary much in that time; but certainly those sent and now before me appear to be the worst-coloured flowers I have ever seen without the variation being either pleasing or acceptable, and I know of but two or three varieties which are worth recognising, and which I will include. *Lælia Perrini* appears to have lost favour amongst Orchid growers on account of its flowers going off somewhat rapidly after expanding; but then its colour is so distinct and so intense that no one can but be enchanted with it whenever seen, and from the fact of its blooming usually in the month of October they are always welcome. It appears to be a native of the Organ Mountain district, in Brazil, and it enjoys somewhat cool treatment during the winter after the flowering season is over, and I advise the plants to be placed in a temperature as near 50 degs. as possible at this time until the early spring, and not to be kept dry enough to cause them to suffer, because I have proved that reduction of temperature is one thing conducive to complete rest, and the one thing that impels strong and vigorous growth and an abundance of flowers. It must be well drained, and its roots should not be encumbered with a great quantity of soil, and this should consist of good brown peat fibre and chopped Sphagnum Moss, raised upon a slight elevation, and the soil pressed down firmly.

L. PERRINI.—This plant has somewhat compressed bulbs, which are oinb-shaped, from 6 inches to 1 foot high, bearing a single oblong dark-green leathery leaf. The flowers are large and spreading, between 5 inches and 6 inches across, sepals and petals a soft, rosy-purple. The three-lobed lip is the same colour as the petals on the obovulate side lobes, the middle lobe narrow and pointed, white or pale-yellow on the disc, with a border of intense deep purplish-crimson, and not a dirty rose-colour, as in the flowers before me.

L. PERRINI ALBA is a gem of the first water, and indeed it seems perfectly wonderful how the typical colours can become so completely obliterated, for in this form the flowers are perfectly white, without a spot or bluish of any kind. It is one of the rare gems to be sought for, and if my readers ever chance to get the offer of a plant they should have it, especially if the price is reasonable, but they must be sure not to be misled by the variety called

L. PERRINI NIVEA, which is also a very charming plant, and it has during the past year or two become more frequent. The flowers are as large as the type, having the sepals and petals of the purest white, and the lip is white or pale-yellow, bordered with rosy-pink.

L. PERRINI IRONATA is yet another form of this plant, having the sepals and petals of a delicate soft rose-colour, and the lip white, bordered with bright light purple, the disc pale-yellow.

I cannot remember to have seen any other forms that are worthy of recording, and such kinds as represented by the flowers sent by "J. E." I would at once destroy, after the blooming season is over, which usually lasts for a fortnight or three weeks; but I have seen the blooms all pass in about a week's time when the plants are removed from a moist house to one with a dryer atmosphere with a view to prolong their beauties; indeed, I am averse to removing the plants from the house in which they are

in the year 1800 it first came to this country in a living state, and I do not think it has ever been absent from our gardens since; beside, however, the original spot from whence it came, further botanical research has found it to be widely distributed over the Indian peninsula, and in various varieties and forms it has been found to exist. One which I think was introduced by Mr. Linden, and called *longira racemosum* was exceptionally good, but the flowers were set somewhat laxly upon the raceme. A variety named *blirmanium*, more recently found by Boxall whilst collecting in Burmah for the Messrs. Low, appears to be a distinct and pretty form. It has smaller flowers than the typical form, and they have the

blooms, some 6 inches to 9 inches in length, the blooms being pure waxy white, tipped with bright rich purple. These will remain in full beauty for three weeks or a month, and the delicious perfume which they yield is very charming. "W. S." appears to be treating the plant quite right for the growing time, but I do not think he reduces the temperature enough to give it a good rest. When I had the best-flowered plants of this kind was after they had passed the winter in a temperature of about 55 degs. to 60 degs., and during this time they had very little water; but in the spring the lowest was about 65 degs., and they had a nice moist atmosphere. You have asked the question in good time; and try my system during the coming winter and let me know the result next May.

MATT. BRAMBLE.

HOUSE & WINDOW GARDENING.

FERNS FOR INDOOR DECORATION.

In reply to several queries regarding Ferns for the house, the plants should not be kept too long indoors, and it would be well to remove them for two or three days into a shady part of the greenhouse from the fernery before putting them into the dwelling-house. The genus *Phlebodium* contains one or two beautiful species for this purpose. *P. aureum* is especially valuable, making fronds some 3 feet to 6 feet in height, deeply pinnatifid, and of a bluish-green colour, the stout rhizome being clothed with large scales. *P. sporocarpium* is another beautiful plant, which grows some 2 feet or 3 feet high, and the fronds are very glaucous. Of the Ribbon Ferns (*Pteris serrulata*) there are many varieties of great beauty, all of which are very suitable for room decoration. *P. tremula* is largely used. There is a beautiful crested variety of this called *Smithiana*, which stands well indoors. *P. longifolia* is another species of great beauty, and to also are *P. cretica* and its variety *albo-lineata*. The variety *Mayi* is even more valuable. Turning from these to the Maiden-hair Ferns, several make delightful ornaments in a room. Among these are *Adiantum formosum*, a tall growing species with beautiful jet-black stems and rich green pinnae; *A. affine*, *A. tenerum*, *A. glaucophyllum*, and *A. cuneatum*. Amongst the *Lomarias* will be found several fine plants for this purpose, *L. discolor* being amongst the most beautiful. For this, however, a certain amount of room is necessary. *L. gibba*, *L. fluviatilis*, a lovely plant, more especially when its fertile fronds are of full size, and many other kinds might be named. *Neottopteris australasica*, with its broad simple fronds, forms a very striking object. *Oxyphium japonicum* is another plant of a light and graceful nature. The *Aspleniums* are a large family, among them being many plants which are very suitable for places of this description, *A. bulbiferum*, *A. dimorphum*, *A. Fabianum*, and *A. plumbosum* being conspicuous amongst the larger growing kinds; while such kinds as *A. fragrans*, *A. Bolanderi*, *A. pulchellum*, *A. Richardi*, *A. myriophyllum*, and *A. formosum* are all very handsome, small-growing kinds. *Todea africana* is also another bold-growing plant with stout leathery leaves, well suited to withstand any amount of draught, as also is *Dicksonia antarctica*, which will be found useful when small. The above-named plants will make up a very nice collection to draw from, and they may be all easily grown into good useful specimens. They should be potted in moderately sized pots, which must be well drained. They should be grown in a nice moist atmosphere and be occasionally syringed overhead.

J. J.

Geznera cinnabarina for a room—

This plant, with very handsome velvety leaves, veined with crimson, surmounted by spikes of scarlet and orange flowers, is one of the most effective of table-plants, lasting long, too, into the winter. *Gezneras* are not so well-known as they should be; they present no special difficulties in cultivation, except that they must be started and grown in the damp air of a hot-house, although they will bear the atmosphere of a room for some weeks when in full beauty. After flowering, the leaves should be allowed to die away gradually, water being gradually withheld until the stems are quite dead, when the pots containing the curious tubers of *Geznera*

A good window Fern—"Pteris cretica."

grown and in which the blooms open, because I think there is more likelihood of their lasting a much longer time if left alone.

MATT. BRAMBLE.

AERIDES ODORATUM.

I AM asked by "W. S." to say something about this plant, which he is very anxious to flower. The speculae, he says, he has had three years, and it grows very well, but it has not bloomed, and from what he says I fancy he is like a very great many of the amateurs, looking more after the propagation of the plant and the dividing it than to the making of it into a good specimen which shall eventually yield a good supply of its deliciously-scented flowers. This plant was first found in Cochin China, I think, more than a century ago, by the Portuguese missionary Loarelro; but some time

tips of the sepals and petals faintly coloured with purplish-lilac. Several fine forms too I have seen under the name of major; but the best and most bold and robust kind which I have seen is the form known by the name of *purpurascens*, which is stouter in its growth, with broader and darker green leaves and stouter trusses of flowers, the raceme too being longer, and the individual flowers larger and the colour more vivid. The worst form I have seen is a kind that makes a very small spike, and with the flowers are very pale-coloured. However, I hope "W. S." has not got this form, but in the event of his having become possessed of it he will find the blooms very sweet-scented. And now for a little about the management of this pretty and easily-grown species (which, when done well, is not easily surpassed). I have had specimen plants which bore annually from fifty to eighty trusses of

should be kept in a warm corner of the conservatory until the spring arrives. Repotted then, much in the same way as a *Tabernaemontana*, and brought on in heat, the plant soon starts into new life and beauty, and will be most useful in table decoration during the autumnal months.—I. L. R.

FREESIAS FOR A WINDOW.

No one who values flowers in winter should be without the *Freesia*, which are easily grown, and most elegant in form also, the flowers being either pure-white or spotted with apricot, which is often the case with seedlings. The secret of success in growing *Freessias* is to pot the bulbs early. They will not do anything if kept long out of the soil, and as they naturally begin their growth during August they should be potted during that month at latest. A compost of leaf-mould and turfy loam, with a little soot and sand, will suit them well, and the pots must be clean, and well drained with potsherds, covered with Moss, sprinkled with about a teaspoonful of soot, which will have the double effect of nourishing the bulbs and keeping away insect pests. Eight or ten good-sized bulbs (they are naturally very small in comparison to the bulbs of other plants) will go into a 5-inch pot, being placed rather low in the soil, to prevent the stems from falling over the edges of the pot, which they are apt to do unless this precaution is taken. *Freessias* will not bear much forcing, and should be grown out-of-doors until the end of September in a sunny place, where they will soon form their "grass," and grow sturdily and strong, when they may be brought into a sunny sitting-room window, where a fire is kept daily, and placed close to the glass, giving as much air as possible, but without a cutting draught, which they will not stand. They need a regular supply of water when they are in their growing stage, and must never at any time become dust-dry. Many amateurs kill their *Freessia* bulbs by neglect after blooming, not knowing that they must still be kept fairly damp then, and allowed to take as long as possible to ripen their bulbs for the next season, for it is during this time of untidiness that they form their blossoms in the bulb. Well-grown *Freessias* should bring two or three fine sprays of bloom from each bulb, and the foliage should be stocky and short, not needing much support. The earliest blossoms open a little before Christmas, and by starting the bulbs each week in August a succession of blooms at the time of year when flowers are most in demand may easily be secured. Of course, the time of blooming will vary with the amount of sunshine and warmth the bulbs may have, but with the help of a fine autumn to bring on the plants quickly through the earlier stages before they are brought in there should be no difficulty in having them open before the new year.

I. L. R.

4559.—Heating a greenhouse.—For heating a greenhouse of the dimensions you give a substantial system of heating is necessary, or in time of severe frost you will come to grief; but however substantial it may be, I cannot recommend you a system that will do with attention only once in twenty-four hours. You cannot do better than fix a boiler of the Loughborough pattern at one end of the house, and have two rows of 4-inch pipes along one end and the two sides.—J. C. C.

Four rows of 4-inch hot-water piping, heated by either a small saddle boiler or a No. 4 or 5 "Star" (upright independent cylindrical)—the latter would require the least attention—would be the best means of accomplishing the desired object. A brick fire, or one composed partly of bricks and partly of 9-inch pipes, would be considerably less expensive in the first place, and work steadily with very little attention, but if carried along three sides of a house of this length rather a lofty chimney would be required.—B. C. R.

Several excellent apparatuses are made by firms advertising in GARDENING. I think you will find the "absorption" heater constructed by Toope and Sons, of Stepney, as good as any.—B. C. R.

Drawings for "Gardening."—Readers will kindly remember that we are glad to get specimens of beautiful or rare flowers and good fruits and vegetables for drawing. The drawings so made will be engraved in the best manner, and will appear in our pages in GARDENING ILLUSTRATED.

FERNS.

THE LADY FERN (ATHYRIUM FILIX-FEMINA).

I AM asked by "A Rambler" if this plant will thrive in town gardens, and where to plant them. Well, I should say this and the numerous varieties which it runs into is the most desirable *Fere* for any amateur to have in his or her garden. There are many varieties of this *Fere*; indeed, I have frequently remarked, when reviving about through vast quantities of it, that any amount of varieties could be obtained, but it would be difficult indeed to get the typical condition of the species now amongst such a vast quantity of forms. Some of these are more curious than beautiful, but some of the kinds are exceedingly pretty, and when growing where their toes can get into the water they form grand ornaments, so that I would advise my friend to make a nicely-sheltered place in the garden for them. This is quite an essential, or else the fronds will produce a broken and ruptured appearance throughout the whole season. Beside shelter, too, these plants require to have ample root room, and a good depth of soil; the kind of soil is not so very particular. If like a good light sandy loam the best of all, and if a running stream can be introduced through it, or if a piece of ground can be utilised in the vicinity of a running stream, you will

Double spathed Arum Lily.

have fully consulted its tastes. It is not an overgreen species, and I have frequently regretted the early disappearance of their fronds, which this season is beginning early; especially is this the case in gardens not supplied naturally with water, but early in the spring the crowns rapidly swell and expand the young fronds, which have such a delicate and charming shade of green that it is almost indescribable, and it is when in this state that shelter from winds is so highly desirable; moreover, shelter at this time means the proper development of the fronds and the beauty and symmetry of the plant for the whole season. "A Rambler" cannot think I shall give him a tithe of the varieties of this beautiful species, but the following are a few of the best and well deserve a place in every garden: *Athyrium Filix-femina acrocladon*, *A. F. f. apiculatum*, *A. F. f. Clarissimum*, *A. F. f. Applehyannum*, *A. F. f. corymbiferum*, *A. F. f. Elworthi*, *A. F. f. Frezillii*, *A. F. f. Fieldii*, *A. F. f. grandiceps*, *A. F. f. glomeratum*, *A. F. f. Orantia*, *A. F. f. Girdlestonei*, *A. F. f. kalothrix*, *A. F. f. multifidum*, *A. F. f. mulliceps*, *A. F. f. pannosum*, *A. F. f. plumosum*, *A. F. f. p. elegans*, *A. F. f. pulcherrimum*, *A. F. f. stidgerum*, *A. F. f. s. oriatatum*, *A. F. f. splendens*, *A. F. f. Versoicis*, *A. F. f. Victoriae*. J. J.

4560.—Catching Rabbits.—The most certain way to catch these beasts out of your garden would be to surround it with strong wire fencing, sunk to about 15 inches in the ground.—A. G. BUTLER.

INDOOR PLANTS.

ABNORMAL FORMS OF THE ARUM LILY.

DOUBLE-SPATHED forms of the *Arum* Lily, as in the illustration herewith, occur frequently with those who grow this plant very strongly. Some years ago I was engaged in working up a stock of these plants, and, in order to raise the required number from the few plants which I then possessed, all the suckers as they appeared were taken off and rooted in small pots. This operation was commenced as early in the season as possible, the young plants being grown on in an early Peach-house. By the middle of June they were gradually hardened off and planted outside in a trench prepared similar to what we use for *Celery*. Many of the plants when placed out-of-doors were strong and well established in 7-inch pots, and the smaller ones in 5-inch ones. In planting, abundance of manure was placed about the roots, and good soakings of water given when the weather was dry. In September the plants were lifted and placed in 12-inch pots, as I could not get the mass of roots they possessed into smaller sizes, using for a compost rich loam and decayed manure. After lifting, the plants were placed behind a north wall and kept well soaked with water and syringed until they were again established. On the first appearance of frost they were housed and kept cool until Christmas, by which time they commenced throwing up their spathe. Towards the end of January and all through the following month more than half the plants produced abnormal spathe. This was attributed to their remarkable strength and the liberal feeding which they received. They did not only produce a solitary double spathe or two, but many in succession during the whole of the season. The same thing has occurred with the strongest *Callas* every year since, but the same plants when not grown strongly only produce single spathe. T.

4566.—Treatment of Hippeastrum bulbe.—The ordinary garden varieties may be grown to flower freely every year, or they may be grown to flower seldom or not at all. They have a decided season of growth and a season of rest. They are now entering into the resting period, and should have no water at the roots from now until they start into growth early next year. They are repotted in January, and placed in a growing temperature, and if they were well cultivated during the flowering and growing season, 90 per cent. or more of them will flower. They begin to flower early in March and continue to do so until the end of April. Sand, peat, and leaf-mould is too light to flower them. The best compost is three-parts yellow loam, one of peat, and one of decayed manure, and a little coarse sand. Do not use large pots. Good-sized bulbs can be flowered in 5-inch and 6-inch pots. After flowering grow them on in a good temperature until resting time in September again. They will make plenty of leaves if grown under the shade of Vines, but few flowers.—J. D. E.

4549.—*Bignonia capreolata*.—You should have no difficulty in getting this plant to flower if grown in a large pot or tub. Seeing that you get plenty of growth, I think you must have cut away in the winter the shoots which would produce blossoms the following season. If there is much growth on your plant now cut half of the shoots away at once, and in the winter reduce the length of those left one-third. The resultant growth from this shortening hack should flower the next season. This is nearly a hardy plant, so perhaps you keep it too warm.—J. C. C.

4562.—Unhealthy Fuchsias and Ferns.—The plants are attacked by thrips, these being the result of an overdry atmosphere and probably an insufficient supply of water at

the roots as well. I cannot remember a season in which greenhouse and other plants required to be so abundantly supplied with water and atmospheric moisture, and so in many cases the supply of water has been limited, insects of this description have been unusually troublesome. Lay the plants on their sides, if possible on some Grass, and syringing the undersides of the leaves thoroughly with moderately strong Tobacco-water, Fir-tree-oil, or some good insecticide, and afterwards with clean water. Repeat the operation twice or thrice until the insects are got rid of, and keep them at a distance in the future by the frequent use of the syringe and maintaining a fairly moist atmosphere above the plants.—B. C. R.

CHOICE STOVE PLANTS.

JASMINUM SAMBAC FL.-PL.

This plant comes from the East Indies; its exquisitely scented flowers are ivory-white in colour, double, the petals much pointed, which takes off the formality in appearance generally present in flowers that have rounded, smooth-edged petals. It is a remarkably free bloomer, but, like most others that continue in flower for a long period, is never clothed with such a profusion at one time as those that produce blossoms from each shoot alternately. The flowers are borne on short, lateral shoots, usually furnished with a few small leaves, that proceed from the axill of the leaves on the stronger growths, which in a healthy plant generally keep on blooming all through the summer and autumn so long as its growth is being made. This is an advantage, as it admits of almost every bit of bloom it makes being utilised for cutting, for which purpose it is the best adapted, as the successional habit of blooming does not admit of its ever making so great a display on the plant as if the flowers opened all together.

CUTTINGS strike easily when they can be obtained with some freedom of growth in them, but the shoots that are disposed to form flowers as soon as they have attained 1 inch or 2 inches in length, even if they made roots, are a long time before they can be induced to grow freely. In the spring, about the beginning of April, cuttings of the right description may generally be had; these should be a few inches in length, but not with the wood too hard or matured. Take them off with a heel and put them singly into small pots three parts filled with a mixture of three-fourths sand to one of loam, the surface all sand; keep moist, close, and shaded in a temperature of 70 degs. or a little more. They will strike in a few weeks, when see them to bear the full air of the house and stand them on a shelf or some other moderately light place. When a fair quantity of roots made move the plants into 3-inch or 4-inch pots, using good turfy loam with some sand. They will now do best with a brisk stove heat, giving air in the daytime with a little shade when the sun is powerful, syringing daily, maintaining a moderately moist atmosphere. After a few inches of growth have been made, pinch out the points of the shoots, for the plant has naturally a thin, erect habit of growth, and to induce the formation of sufficient branches it is necessary to resort to stepping, although it is by no means desirable to attempt to restrict it to a bush-like form. It is best

ROWN ROUND A PILLAR or wound round a few tall stakes inserted just within the pot; being a spare rooter, it must not have too much room, either in a pot or planted out. In July move them into pots 3 inches or 4 inches larger, and again step the shoots. Treat generally through the summer as recommended until the middle of September, when cease shading, give more air, less moisture in the atmosphere, and reduce the temperature; during the winter 60 degs. or 65 degs in the night will be enough, only just keeping the soil a little moist. Towards the end of February increase the warmth, and when growth has fairly begun again pinch out the points of the shoots, and move to pots 2 inches or 3 inches larger. In the matter of heat, moisture, air, and shade treat as in the preceding summer; they will this season bloom from all the growths they make. When planted out, the soil to which their roots have access must be limited to a small space, or it will most likely get snar. If confined to pots, all they want in subsequent years is to give more room as it is

wanted, not attempting to shake out the plants or disturb the roots more than can be avoided. A little manure-water in a weak state will be an assistance. The plants will last for many years. There is a single-flowered form of this Jasmine differing little in its appearance, except in the flowers. It succeeds under similar treatment to the kind under notice. This Jasmine is liable to the attacks of most insects that affect plants grown in hot. Thrips and red-spider, which are partial to the leaves, can be kept down by syringing. If any insects of a worse description, such as scale or mealy-bug, make their appearance, sponge with insecticide, finishing with clean water.

4522.—An Ivy-leaved "Geranium."—Set the plants outside in the sunshine to ripen the growth, but take indoors before frost comes.—E. H.

The best plan will be to cut out all the dead and some of the weak wood next, and if it seems to require it to cut it down as low as you like in the spring, about April. It is rather late to cut such a plant in a cool house hard back now, it might kill it, but in the spring it may be safely reduced to any extent, and will quickly break out and commence flowering again.—B. C. R.

4531.—Tortoise stoves for greenhouse.—A small form of this stove would give you all the warmth you require to heat a greenhouse of the size you mention, but are you aware that the dry heat of this and similar stoves is altogether unsuitable for plants? An occasional fire would not do much harm, perhaps, but if kept alight regularly the foliage of most plants would soon get covered with dust and die away. It would be better to use an oil-bump, and only light it on frosty nights.—J. C. C.

I have no great faith in this stove myself, and indeed there is as yet no wood next, and if it seems to require it to cut it down as low as you like in the spring, about April. It is rather late to cut such a plant in a cool house hard back now, it might kill it, but in the spring it may be safely reduced to any extent, and will quickly break out and commence flowering again.—B. C. R.

4567.—Violets in frames.—The best and only sure method of obtaining plenty of Violets in winter is to plant out the runners singly in April, to rich ground, keeping them well watered. By the autumn each will be a strong clump, which may be potted or simply "laid in" in the frames. Old or starved roots never do much good; the runners should be cut off.—B. C. R.

Place a cold frame in a sunny position and protected also from north and east winds. Place sufficient faggots or old Pea-stalks at the bottom of the frame that will raise the plants close to the glass, allowing for 9 inches of soil. The wood provides ample drainage for surplus water. Anything approaching waterlogging about the roots is detrimental to the development of the flowers. Over the wood lay a thin covering of litter to prevent the fine soil running down among the wood. Road-scrappings are useful for mixing with good garden soil, decayed vegetable refuse, and rotted leaves, as they contain much grit, which the roots of Violets are partial to. A moderately-light but not overrich compost should be prepared. Lift the plants from the ground with a trowel, retaining a small portion of soil with the roots. If the plants are large, having several crowns, all the runners should be poked off, but if they are small plants let the runners remain. Give sufficient space between the plants that the leaves of one will touch those of its neighbour. Give a good watering to settle the soil about the roots, but do not put the lights over the plants until there is fear of frost injuring the leaves, and then tilt them when raining, and when hot, and the thermometer out-of-doors stands above 35 degs., pull the lights off altogether, the object being to give the plants as much air as possible to induce a stocky growth. Although a degree or two of frost will not hurt the Violets it is not wise to expose them to it—the foliage ought to be preserved intact; a lining of long litter or freshly-gathered leaves will protect the outside of the frame; a double thickness of ordinary mats over the glass will suffice in that part. But little water will be required during the winter, although the plants must not suffer for want of it. Next April the plants should be pulled in pieces, planting them out again on a west border. The present is a good time to place the roots in the frames.—S. P.

4570.—Gloriosa superba.—The tubers of this plant will sometimes lie in the ground a long time before they start into growth; but as long as these remain fresh they may be expected to grow sooner or later. This is not the best time for them to start; it is the worst in fact. I would let the bulb remain where it

is. Keep it in a warm-house temperature, not too hot. Give no water. Pot the bulb again in the spring, and start it to grow in a nice bottom-heat in the forcing-house.—J. D. E.

I am of opinion that a great deal more fuss has been made over this plant than it deserves when cultivated in this country. I cannot see any great beauty in a bunch of flowers placed at the extremity of a long twisted growth, with the foliage often of a yellowish, sickly hue, owing to the roots heaving had too much water and not sufficient warmth. With regard to the bulb to which this question refers, its remaining dormant for so long is not altogether contrary to experience. That being so, no further attempt should be made to induce it to grow this year. Do not give it any more water, and lay the pot on its side on the floor of the house, where the temperature is not less than 50 degs. Next year repeat the same treatment in the spring as you did last.—J. C. C.

4580.—A greenhouse for profit.—Unless the plants have already been prepared there would not be any chance to grow flowers for profit. These who sell flowers in the winter have to prepare the plants that are to produce them in the summer. Chrysanthemums are good winter flowers and can be produced without heat, or at least enough to keep frost out. The white varieties, such as Lady Selborne, Mrs. Rundlo, and Lord Eversley, for the latest should be grown. White and Red Carnations, such as Madame Carl, Mrs. Moore, and Winter Cheer, would be the best. The White Roman Hyacinths are also excellent winter flowers. Rhubarb could be forced under the stages, and the flowers could be grown above it. Many persons make a profit by selling plants of the Chinese Primula.—J. D. E.

Rhubarb will perhaps pay as well as anything if there is a local demand, but after the fuel is paid for there will not be much profit. As prices are now small houses will not yield much profit.—E. H.

4571.—Phygelanthus albens.—I am not surprised to hear that you failed to get this plant to flower, as no doubt you gave it too much heat and not enough air in summer. Thirty years ago I flowered it beautifully trained to the roof of a conservatory, in which the winter temperature did not exceed 50 degs., and which was well ventilated in summer. It is not a suitable plant for small houses or for amateurs, and as it is possible that the cold nights we are having will have injured your plant, I cannot recommend you to devote any more time or space to it unless you have plenty of the latter. If you decide to take it under glass again you must do so at once, but I am afraid the disturbance to the roots will cause the flower-buds to wither away.—J. C. C.

4555.—"Geranium" outtings.—The only way you can hope to succeed in wintering these without artificial heat is to set the frame on a firm, dry bottom of ashes, &c., in a very sunny and sheltered spot, say in the angle of two walls facing south and west. Bank up the sides well, on the first approach of cold weather, with ashes or turf-sods at least a foot thick. Ventilate the plants abundantly on all fine warm days, but close the frame before the sun goes off it, and if even a slight frost appears probable cover the glass well with mats, old coats, carpets, or the like. In very severe weather place two or three thicknesses of the above on the glass first, then a foot of straw or dry Fern (Bracken), and a piece of thick tarpaulin or some waterproof material over all to keep the whole in place and dry. The outtings must have been struck early, be well hardened, robust, and thoroughly established in the pots, and from October till March should have only a very little water in the forenoon when the weather is very mild and sunny, and none whatever in frosty weather. Ventilate whenever safe to do so, but close and cover up in good time, and do not uncover too soon after the frost is gone. If your locality is fairly mild, and the winter not very severe, you may hope to save most of them. But contrast this with the treatment of Tuberosa Begonia, which may be started away for the winter in a kitchen cupboard.—B. C. R.

Do not keep the outtings in such a frame, but you will have to protect the plants in severe weather by heavy coverings of straw or mats. But it would be far better if you have

a frame heated only just sufficiently to keep out frosts, to put the cuttings in that, than in a cold frame, because there will be great treble in winter, especially if so prolonged or severe as recent ones, to preserve them from frosts, which will soon settle them. Only a little heat is required, and it is essential also not to keep the soil wet. During the winter, when cuttings are required only for hedging-out next spring, the great point is to get them well hardened, and to this end the soil must be almost dry, only giving water when really necessary, otherwise you will lose a quantity through damping off. A humid atmosphere promotes decay. Remove all decaying leaves, and on fine days let in a little air in the midday, so as to maintain the air in a sweet condition. As the spring comes the plants should be repotted and then grown on.—C. T.

Much depends upon the condition of the cuttings. If they are in a firm, well ripened condition and well rooted, they will not be so likely to damp. Plunge the pots in dry ashes before the approach of winter. Ventilate freely whenever the weather is favourable. Whenever watering is necessary, give it on fine bright days, and leave the lights off for two or three hours afterwards to dry up damp, and do not spill a single drop of water about the frame. During frosty weather keep the plants dry, and if the frame is not uncovered for several days during frost they will take no harm if the frost is kept out. To keep out frost, surround the frame with ashes as dry as they can be obtained, or long, dry litter will do. In ordinary weather double mats on the frame will be sufficient, but when frost sets in cover the mats with dry litter or Ferns over the mats. A waterproof covering over the litter will be an advantage.—E. H.

You had better not attempt it; you will be certain to meet with disappointment. A deep frame fitted with shelves, a small oil-lamp, and a chimney to carry off the fumes of the oil might answer somewhat as a small greenhouse would, but I should imagine that even then the plants would be apt to get mouldy and damp off.—A. G. BURMAN.

Compost for the Oleander.—So long as this is fairly rich and upon it does not so much matter what it consists of. Peat, leaf-moss, and loam, in equal proportions, will answer splendidly. Let the pots be thoroughly drained, as, although a water-loving subject, and partial to liquid manures, the Nerium Oleander greatly objects to anything approaching stagnation.—P. U.

POULTRY & RABBITS.

Breed of poultry.—I, I fear no poultry keeper will admit that there is any heat breed of poultry for the tables, for each variety has its admirers. The various breeds of Dorking or Game, or Indian Game, are however all in the front rank, and it is possible that individual strains of either would be pronounced by the best judges to be all that can be desired. A cross between any two of the foregoing would produce chickens of really excellent quality. 2. This is a question of strain as regards the laying properties, but, in past years, the Houdan would be likely to take the palm, since it was at that time an excellent layer and no one could complain of its table qualities. If we are asked to select another fowl to meet the quietest requirements in this section, I should suggest a cross between some really good layer, such as the Leghorn or Minorca, and one of the breeds mentioned above. 3. Game or Dorking are generally considered the best mothers, as they take great care of their offspring, and brood them for several weeks. It rarely happens either that these hens leave their nests whilst sitting. The heavier fowls, Cochins, Brahmas, and the like, are also good sitters and mothers, but some people think them cumbersome. Half-bred hens with one of their parents of a non-sitting breed will generally all well, but they are often flighty, and a hen that is too active is seldom a really good mother.—DOULTING.

Feather-eating.—It is not usual for fowls that have a good Grass run to eat each other's feathers, although I have had it occur in my own experience during dry, hot weather when worms and other food of this kind could not be obtained. They will discontinue the practice after rains when their usual food becomes more abundant; but if they persist in the practice through sunshine and showers, summer and winter, there is to be done but to kill them.—J. D. R.

RULES FOR CORRESPONDENTS.

Questions.—Queries and answers are inserted in *GARDENING* free of charge if correspondents follow the rules here laid down for their guidance. All communications for insertion should be clearly and concisely written on one side of the paper only, and addressed to the Editor of *GARDENING*, 37 Southampton-street, Covent-garden, London. Letters on business should be sent to the Publisher. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Unanswered queries should be repeated. Correspondents should bear in mind that, as *GARDENING* has to wait a press some time in advance of date, they cannot always be replied to in the issue immediately following the receipt of their communication.

Answers (which, with the exception of such as cannot well be classified, will be found in their different departments) should always bear the number and title placed against the query replied to, and our readers will greatly oblige us by advising, as far as their knowledge and observations permit, the correspondents who seek assistance. Conditions, soils, and means vary so infinitely that several answers to the same question may often be very useful, and those who reply would do well to mention the localities in which their experience is gained. Correspondents who refer to articles inserted in *GARDENING* should mention the number in which they appeared.

A new lawn.—Should a newly-covered lawn be covered with burnt lime and then manure, and the best time to do this?—SOUT.

Azalea in a window.—Will someone please to let me know the best treatment to give an Azalea I have outside my window? Should I take it inside on the appearance of frost?—J. M.

Tuberoses.—Will someone kindly tell me what to do with the bulbs after they have died down? Ought they to be kept in the pots, or dug up and put in silver sand during winter?—M. K. M. G.

Laying out a small plot.—How should I best lay out a small plot from front gate to house, about a foot or 18 inches broad, and perhaps 5 yards long, next to a brick wall, and facing south?—SOUT.

Plants and insects.—My Peas and Beans have been nearly eaten up by grubs of some sort which seem to come out in the night. They have also finished the Peas. Will someone kindly suggest anything to prevent this?—SOUT.

Olema for a trellis.—Will someone kindly tell me the most suitable kind of Olema to cover a trellis, and also to make an arch over a path, facing south? The soil is of a poor dry nature. Also what would be the most suitable dark-red climbing Rose for a cold-house.—C. P.

Peat for Azaleas.—Would "O. T." kindly inform me how deep a peat bed should be for Azaleas? I propose to make it of peat and vegetable refuse in equal parts. My soil, a red loam (Oxfordshire oolite), would not, I think, grow them well. Rhododendrons live, but do not flourish.—A. C.

A new garden.—To a garden made this spring the soil is exceedingly full of worms. It was covered with horse-mansure in May, and this has since been worked into the soil by the spade. How can I get rid of them? What time of year is best to put manure on small growing small (fruit and garden trees) and flowers, and should lime be put on?—SOUT.

Fern-case.—I lately bought a large Fern-case, and planted therein six Maiden-hair Ferns, two Hart's-tongues, and one Pteris, all of which died away, with the exception of two of the Maiden-hair. I noticed when planting that there were no holes for drainage. I covered the bottom with slanders, and put brown peat on top. North-west aspect. A few hints on management would oblige.—J. MARTIN.

To the following queries brief editorial replies are given; but readers are invited to give further answers should they be able to offer additional advice on the various subjects.

Epidendrum vitellinum majne (Chr.).—There appears to have been a great diversity of opinion this season about the proper treatment of this beautiful plant, but as you ask which is right all I can say about the matter is that I certainly favour the side that goes in for a low temperature, shade, and a very damp atmosphere.—M. B.

Poison Cake of North America.—J. Kibben asks the name of these plants, and he wants to know their effect; I am sorry, because these effects are not the same upon everyone. The plant is, I think, more correctly called the Poison Squash, and there are several species in the States, which are blamed for the same properties. They cause great irritation, I believe, but perhaps the plant does not develop the same properties in this country; but one thing is certain—I have never found any ill effects from handling growing plants.—J. J.

Epidendrum Tovaronee (Judg.).—Thanks for sending me flowers of this species. I suppose I must goon the high-art principle—that is when you see a painting that looks black or dark you must draw the conclusion that it is white, and these flowers of Tovaronee being black I must suppose them to be pure white; but if they were their true colour they would not be worth anything. The other plant appears to be a very small-flowered and very poor-coloured variety of E. scoparium. I would burn it. That is all it is worth.—M. B.

Oncidium incurvum (Thos. Cole).—I have no doubt that you are tired of waiting for these spikes to open, but it is of no use getting tired; you must wait yet a little longer, and then the flowers will unfold, and reward you with their grace and beauty, and regale you with their delightful perfume. You have it in quite a suitable temperature, and I kept mine you have only to make a little more shade, but it is a plant which does not do very long time to develop, and did you get the spikes to send it.—M. B.

Lycaste Harrisiana (G. Collins).—This is the name of the very fine flowers you send, and I would ask you if it is not a perfect beauty? It has been in cultivation about seventy years, and it is to be found under the name of maxillaria, Bifrons, and even Donna Lindley, however, removed it to the genus Lycaste, and under this name it is now frequently to be found. It appears to be a native of Brazil, and it thrives best in the Cattleya-house, but it will and does grow well in a cooler house, but it does not bloom so abundantly.—M. B.

Fern Caterpillars (S. J. T.).—It appears to me that you have a good stock of two kinds, one is the larva of the Silver-Moth (Pleukis gamma), the larger one being that of the Amphirades Moth (Phlogoporus artionous). They are both very destructive to Fern fronds, and indeed to any low-growing plants, and from the fact of their getting such a size here you had noticed their ravage gives me an idea that you must have been away from home at the sea-side. Well, you had better search carefully for all you can find, and smash them all as found. Your neighbour's plants will mature enough to perpetuate the species.—J. J.

Mitonia spectabilis (Dorothy).—This plant now presents, I have no doubt, a very pretty sight, having seventeen flowers open. You say it is growing upon some rockwork in the stove, but what can you do to prevent it getting so yellow (enclosing some leaves for me to see)? The gardener tells you it must not be shaded as it will not grow. Well, your gardener tells you about right, but another reason got him to try a little shade in order that the Orchid may not present such a wabegone appearance; but it is quite the nature of this plant to turn yellow. I have grown them greener than your plant, but I think it has been at the expense of some flowers.—M. B.

Rockwork for public parks.—Mr Edmunds writes asking if it is possible to construct and utilize rockeries for Ferns and alpine in Brockwell Park and other similar places, and if they could not be built and planted in such a way as to be useful and attractive to the many who use these places? Quite so, this is a subject that should occupy the minds of those in authority. We cannot all make a journey to Kew Gardens to see the Ferns and alpine plants, and I should like to see such places extended. I speak rather interestedly, for the park in question is contiguous to my residence, and I should be glad to see my correspondents's wishes carried out.—J. J.

A yellow Lady's Slipper.—J. B. asks if there is such a thing as a good yellow-flowered kind, to which I have answered yes, but I do not think it would be of any use to cross with any of the orange-leaved section. I include in this material to the kind known as Flor del Pelloano, or Politan-downer, Cypripedium, which is a terrestrial plant belonging to the same section as the Moccasin-flower at the Northern States of America (C. spectabile), and these two sections have never been known to cross, but there is a yellow-downer plant belonging to the same section—viz., C. Druryi, the segments having a dark band of chocolate down the centre of each.—M. B.

Microlepta hirta orlatata.—T. J. B. sends me a frond of this Fern which he says he turned yellow within a few days, and I am the more struck with this statement because he says the same remark was made to me of this plant only a few days ago by Mr. Watson, a writer of this paper, and I think it must be the odd nights we have had lately. However, there may be something to say on the other side, and it may be suffering from the effects of drought on some previous occasion. Do not confine its roots to a small pot, for it is a strong rooter, and it will soon grow into a handsome specimen if kept in the stove-ferner, and duly supplied with water to its roots, and the atmosphere also nice and moist.—J. J.

Epidendrum prismato-arpurum.—C. G. sends me a flower of this plant, which he says came to him last year through the death of an uncle, and this is the first one of the whole lot that has flowered, and he asks should it be grown cold or hot. Well, I would advise you to keep it where you have flowered it, because the fernest plant I ever saw of this species was growing in the East Indian house, although I usually took upon it as a cool plant, and it is found in Central America at an elevation of some 5,000 feet, so that, in fact, it will grow cool, but, as before remarked, it will thrive, and grow well too, in heat. I am not surprised that you should be in love with it, having three good spikes open, but the one flower does not lead to much satisfaction. A few years ago it was thought a great deal of, but it is not held in so much esteem, although the combination of colours is quite exceptional. It requires to be well drained, and potted in rough peat-fibre.—M. B.

NAMES OF PLANTS AND FRUITS.

Any communications respecting plants or fruits sent to name should always accompany the parcel, which should be addressed to the Editor of *GARDENING* Illustrated, 37, Southampton-street, Strand, London, W.C.

Names of plants.—T. C.—1, *Leila* Dayana; 2, *Cattleya intermedia*; 3, *Cattleya Harrisiana*; 4, *Burillingtonia venosa*,—George Cypher.—1, *Sison Anomum*; 2, *Lythrum salicaria*; 3, *Rubus fruticosus*.—C. P. C.—No, the figures must be reversed, 2 is the true *Oncidium Papilio*, 1 is *O. Ramezanianum*.—Charles M.—The *Begonia* are very pretty, but we decline the task of naming. Go to Lasing or to Cassell—both are experts.—T. Dickson.—1, *Chelidonium majus*; 2, *Neottia australis*; 3, *Salpiglossa volubilis*; 4, *Blotopogon japonica*; 5, *Selligera andromorfe*; 6, *Nephrrolepis exaltata*.—T. Record.—1, *Cattleya gigas*, a very nice variety; 2, *Cattleya Gaskelliana*.

BIRDS.

Food for Doves.—Will someone kindly inform me what is the proper seed food for doves, and what green food is good for them?—LESLIE LEBROCK.

Cramp in a bird's legs.—Would anyone kindly tell me what would be the best cure for cramp in the legs of a mole bird between Goldfinch and canary? My young mole bird is one of the third hatch this year, and it has now legs as tender as water, and crippled with cramp in the legs.—J. J.

CHRYSANTHEMUMS.

EARLY-FLOWERING CHRYSANTHEMUMS IN TOWN GARDENS.

ONE of the most successful exhibitors of early Chrysanthemums at the recent show of the National Chrysanthemum Society at the Royal Aquarium was Mr. D. B. Crane, of Highgate, who is a well-known amateur grower of the flower. It will interest readers of GARDENING, doubtless, to know something of the culture pursued by this grower, and his remarks are likely to prove useful to others who live near large towns, but wish to get Chrysanthemums in full beauty in early autumn. He mentions that the good qualities of the early-flowering Chrysanthemum are very little understood generally, and this, I think, is very true. And also, Mr. Crane says that it is quite a mistake to suppose that there is so much sameness in the coloring and form of the flowers as some declare is the case. Many excellent kinds can be obtained, and the colour and forms all that is to be desired. These are being added to each season, thus making it quite an easy matter to prepare a list calculated to satisfy the opponents, if any, of this most useful and charming flower. Their cultivation is very simple; indeed, any time between the end of February and end of March may be taken as the correct time in which to propagate. The cuttings should be placed around the edge of 3 inch pots, and transferred to a cold frame, or, better still, in a cool greenhouse. They will not bear very readily, and in the course of three weeks or a month may be potted off singly into thumb-pots. The best compost for the potting is made up of two parts fibrous loam and one part leaf-soil, with sufficient coarse sand to keep the soil nice and open. The object of the grower should be to produce good and strong plants. This is best accomplished by placing them in a cold frame facing south, and after they have recovered from the check received in repotting, admit as much air as possible. On first days the lights may be entirely removed, and as the plants fill the pots with roots they should be potted on into larger sizes, according to the vigour of the roots. This may easily be seen by turning out the plants at any time. When repotting, one part of rotten manure may be added to the compost used at the previous shift. About the end of May or beginning of June the final potting may be commenced. A good compost is made up as follows: Two parts fibrous loam, one part rotten manure and leaf-soil, with coarse sand added to make the whole porous. To every bushel of soil add a 6-inch potful of dissolved bones and bone-meal in equal proportions, or any other equally concentrated soluble manure. Mix thoroughly, and pot when the compost is nice and moist. "Cropping" must be done very carefully, arranging the pieces in proper order; oyster-shells may be used for this purpose, with advantage. Stand the plants out in positions where the wood may become well ripened, and tie the shoots carefully, as many of the varieties

are so free blooming that support of this kind is absolutely necessary.

FOR BEDS AND BORDERS the plants may be put out in May, and carefully etaked and tied. This form should be tried by those who have not the time and convenience for growing them in pots. Many plants will in this way commence to bloom in July, and give a profusion of flowers until severe frosts cut them down. A few degrees of frost will scarcely harm them, while Dahlias and kindred subjects are damaged beyond recovery. Hence the great advantage of the early-flowering Chrysanthemums for border culture. A selection of varieties may be made from the following: Of the Japanese class the finest are Mme. C. Desgrange (white), and its sports, Mrs. Burrell (primrose-yellow), G. Wermig (bright-yellow), and Mrs. Hawkins (deep-yellow); Lady Fitzwygram is a very dwarf-growing plant, with huge white flowers. Other good kinds are Mme. la Comtesse Foucher de Caril, very free blooming, the flowers orange-yellow; M. Ostave Grunerwald, dwarf growth, the flowers mauve, with broad petals; Pynaert Van Geert (yellow, tipped with crimson), E. Rowbottom (large yellow flowers), Vice-President Hardy (yellow, flushed with orange), General Hawker (amaranth), and Sam Barlow (lilac-mauve, shaded with yellow, white centre, and a remarkably free-blooming kind). For the purpose of cut flowers the best-flowering Pompons are most useful. The best of these are Lyon (amaranth, the flowers comparatively large), Alice Butcher (orange-red, tipped with gold), Mrs. Cullingford (white), Miss Davis (blush-pink), Piercey's Seedling (orange-yellow, the plant very free blooming), Blushing Bride (blush, very free, bearing two displays of bloom), Strathmeath (mauve, the plant of excellent constitution), Flora (bright-yellow), L'Anide Condorhet (very bright-primrose, beautiful form), Early Blush (blush, a very early-flowering variety), Mme. Jollivart (white), and Martinmas (the flowers large and of a mauve colour, edged with white). With such a list of varieties as that given above there should be little difficulty in making a suitable selection. Mr. Crane says that to those who have hitherto failed to interest themselves in the early-flowering Chrysanthemums, let them give some of the above varieties a fair trial.

V. C.

New Cactus Dahlias.—This class is always having come fine variety added to it, and this season several very beautiful novelties must be made note of. The first is lady Penzance, and it is a pleasure to see that each year the flowers lose that coarse and objectionable character which distinguished those kinds called "decorative." The colour of the variety Lady Penzance is soft yellow, and the petals are pointed, not too broad, but composing a very pleasing and refined bloom. Lilacina is a distinct kind, the flowers shot with mauve, purple, or a yellow ground. The only danger in getting such kinds is importing magenta tones into the flower, which are not pretty. A variety which I think will be largely grown is named Mr. A. Peart, and is a white Cactus variety—at least, a deep colour, the centre suffused with yellow. This is a welcome addition, and we may reason-

ably expect before long quite a pure-white flower, as pure as the Pompon White Aster, which is perhaps the most popular Dahlia in cultivation. Very distinct from this is one named Matchless, which is best described in deep-mauve purple, with a suspicion of crimson on the margin of the petals. It is one of the deepest-coloured purples in cultivation. A light-coloured flower is that named Lady Henry Grosvenor, in which one gets somewhat the character of that gem of all Cactus Dahlias named delicate. The flowers of the variety Lady Henry Grosvenor are touched with salmon-rose, the ground yellow, a very beautiful association of quiet colours. Chancellor, another fine novelty, has a rich-crimson flower, the edge of the petals crimson. It is interesting to know that this class is founded upon that well-known kind Jubarezi, which was introduced from Mexico about 1879. The newer varieties hold their flowers up better above the foliage, and are freer.—V. C.

4509.—Cuttings of "Geraniums" and Fancies.—Loss no time in taking cuttings of the former. Short, stocky shoots, 4 inches long, are the best, removing the bottom leaf and cutting square across just below the joint. Dibble them singly in 2½-inch pots, or four cuttings around the edge of one pot, 3½-inches in diameter, using sandy soil. Give a good watering to settle the soil about the cuttings, and stand the pots in the shade out-of-doors for a few days to prevent flagging of the leaves too much. Afterwards remove them full in the sun. Here they may remain until there is danger of frost injuring them, when a place in the greenhouse, on a shelf close to the glass, will be the most suitable. Cuttings of Fancies need not be taken until the first week in October. Short, stocky shoots springing up from the base, 2 inches long, that have not flowered, are preferable to the soft, sappy stems of those shoots have borne flowers and are now hollow. Dibble the cuttings thickly in sandy soil in an ordinary seed-pan, with a few crocks at the bottom for drainage, placing the pan in a cold frame. If a quantity are required lay 4 inches of sandy soil in a shallow frame on a bed of coal-ashes made firm, and give a gentle watering to make the soil firm. Dibble in the cuttings 2 inches apart, give another watering, and keep the frame nearly closed, shading the cuttings from bright sun for a few days. Tilt the light for an hour occasionally to dissipate condensed moisture settling on the cuttings. Directly roots have formed admit air to the frame in quantity to induce a stocky growth. Pinch out the point of each plant when 3 inches high to prevent them becoming drawn up weakly, and to induce side shoots to push from the base. Gooseberries are easily propagated from cuttings from the current year's shoots taken off early in November, 10 inches long, nip out the point, and remove all the buds from the base upwards, except four or six at the top of the cutting. Insert them in rows 10 inches apart and 6 inches in the row, on any open part of the garden, making them quite firm at the base. On the soil between the rows lay 2 inches of coal-ashes to prevent the roots becoming the rotting by upheaving the ground.—S. P.

TREES & SHRUBS.

THE MAGNOLIAS.

In reply to queries: About a score species of Magnolias are known to botanists, and all but some half-dozen or so are in cultivation in this country. The head-quarters of the genus are in China and Japan, a few are peculiar to the Himalayan region and a few more to North America. All are handsome and desirable trees or shrubs; some, indeed, may be classed with confidence amongst the most beautiful objects to be met with in the gardens of temperate climates. A glance at a fine specimen of the Yulan (*Magnolia conspicua*), of China and Japan, when in flower will show what glorious effects may be obtained in spring in the South of England, at any rate, by its use. It is true enough, unfortunately, that frosts sometimes injure the flowers and change their snowy whiteness into an unsightly brown. Perhaps the reason that this *Magnolia* and its allies are not more frequently met with in gardens is owing to the fact of their not transplanting readily. The best results obtain if the plants are procured and planted just as

height of from 80 feet to 90 feet, with a trunk from 2 feet to 4 feet in diameter. The yellow Cucumber-tree (*M. cordata*) is regarded by Professor C. S. Sargent in his magnificent work, "The Sylva of North America," as a variety of *M. acuminata*. It is a rare plant in a wild state, as it does not appear to have been collected since Michxer found it in Georgia.

M. CAMPBELLI, one of the most gorgoes of Indian forest trees, has not fulfilled the expectations of those who took so much trouble in introducing the species to British gardens. In a wild state it attains a height of 150 feet, and the fragrant flowers, varying from deep-rose to crimson, are preceded before the leaves appear. Probably the finest specimen in the British Islands is the one at Lakeleude, near Cork, which ten years ago was 35 feet high. Perhaps Mr. Gemblont would be good enough to inform us what progress the tree has made since then. In 1881 it flowered for the first time, and a figure was prepared for the *Botanical Magazine* from material forwarded to Kew by the late Mr. Crawford. Considering the beauty of *M. Campbellii*, it would appear worth while to treat it as a wall plant against some high building in a warm sunny position. As it

spathulate leaves auricled at the base; they each measure about 8 inches to 1 foot in length, and about 3 inches or 4 inches across at the widest part. The flowers, each of which measures 3 inches or 4 inches in diameter, are creamy-white in colour, and are produced later than those of any other cultivated species. In a wild state the tree attains a height of from 30 feet to 50 feet.

M. GLAUCA, the Laurel Magnolia or Sweet Bay of the Eastern United States, is a delightful evergreen shrub with oblong or oval leathery leaves, bluish-green above and silvery below. The flowers are globose in shape, very fragrant, opening of a rich-cream colour and gradually acquiring a pale-apricot tint with age. In a wild state this species occurs in swamps and attains a height of 20 feet. A large-flowered form (*M. Thompsoniana*) originated, according to London, about eighty years ago in the nursery of a Mr. Thompson at Mile End. It is figured in the *Botanical Magazine* as *M. glauca* var. *major* and in other publications. By far the most faithful and characteristic representation, however, is given in *Garden and Forest* for 1888. Professor Sargent there says: "It has been considered a large-flowered variety of *M. glauca*, and by some authors a hybrid between *M. glauca*, and *M. Umbrella*. It is probable that the latter supposition is correct, as, although the leaves of *M. Thompsoniana* cannot be distinguished from those produced on a vigorous plant of *M. glauca*, the leaf-buds are quite glabrous and destitute of the silky hairs which cover those of that species, while the broad, strap-shaped, reflexed sepals and obovate-oblong petals, contracted into a narrow olew, distinctly belong to *M. Umbrella*; the flowers, rather more than 6 inches across when fully expanded, being intermediate in size between those of the two species. They have, on the other hand, the delicious fragrance peculiar to those of *M. glauca*. So far as I know, *M. Thompsoniana* does not produce fruit, and it is a serious fact that it is much less hardy than either of its supposed parents, suffering here always unless carefully protected in winter, and rarely rising above the size of a small bush, although Loudon . . . speaks of trees at Mile End more than 20 feet high. I shall be glad to see fruit of this plant, and to learn if it grows more vigorously in Europe than it does in this country."

M. GRANDIFLORA, the great Laurel Magnolia of the Southern United States, is—in England—best treated as a wall plant; under these conditions it thrives well and flowers freely. In order to form some idea of the beauty of this species it is necessary to see it in large symmetrical stately trees in the West of France, &c., where climatic conditions obtain which more nearly approach those of its native habitats. In "Bartram's Travels" that enthusiastic lover of Nature exclaims: "Behold you promontory, projecting far into the great river, beyond the still lagoon, half-a-mile distant from me. What a magnificent grove arises on its banks! How glorious the Palm! How majestically stands the Laurel, its head forming a perfect cone! Its dark-green foliage seems silvered over with milk-white flowers. They are so large as to be distinctly visible at the distance of a mile or more. The Laurel Magnolias that grow on this river are the most beautiful and tall that I have anywhere seen, unless we except those which stand on the banks the Mississippi. . . . Their usual size is about 100 feet, and some greatly exceed that. The trunk is perfectly erect, rising in the form of a beautiful column and supporting a hood like an obtuse cone." In *The Garden*, Vol. II., p. 205, there is a fine illustration of the "Magnolia grandiflora at Home." Professor Sargent, in his "Sylva of North America," adopts the name of *M. foetida* for this species. In *Garden and Forest* for 1889, one writer urges the claims of this species as the national flower, and states that it "was among the favourite trees, if not the especial one, of Washington. An imposing specimen over 75 feet high, known to have been planted by his own hands, still flourishes at Mount Vernon, and every year since this modern Mecca has been accessible to the public, each fallen petal of its faded blossoms, every glossy leaf of its rich foliage and every seed that drops from its fruit-pods have been carried away as precious souvenirs by the visitors to that hallowed spot."

Magnolia obovata. Engraved from a photograph sent by Mr. E. E. Peacock, Bewdley Villa, Bath. (See page 421)

growth begins in spring. The fleshy roots when injured rot rapidly, and when autumn planting has been practised, very many individuals succumb to the ordeal, those that do not do so outright often struggling on in a pitiful plight for years. A little care in transplanting in spring, in sheltering with mats from dry winds or hot sun, and in syringing the wood to prevent shrivelling until the plants are thoroughly established, would do much to prove that the Magnolias can be planted with every prospect of success. Some species occasionally ripen seed freely in this country, and it is well worth while to sow this seed at once. If dried and kept like other seeds until the following season, all chance of germination will have passed. All the species of the natural order Magnoliaceae have seeds which retain their vitality but a very limited period.

M. ACUMINATA (the Cucumber-tree of the United States) makes a noble specimen when planted singly in the park or pleasure ground. It is deciduous, the leaves varying from 5 inches to 1 foot in length and glaucous green, the flowers yellow-tinged, bell-shaped and slightly fragrant. There are fine examples of this tree at Kew, in the garden of Syon House, Hampton, &c. In its native habitats it attains a

occurs in a wild state along the outer Himalayas at elevations of from 800 feet to 1,000 feet above sea level, there seems every probability that the treatment suggested would prove successful.

M. CONSPICUA.—In its typical form this has snowy white flowers, which are preceded in the greatest profusion in the latter part of April and beginning of May. Splendid specimens of this beautiful Chinese and Japanese tree are to be seen at Gunnersbury House, Syon House, Kew, &c. *M. Yulan* and *M. picea* are names under which this is found in some books and gardens. Several hybrid forms between this species and *M. obovata* occur in gardens; of two of these, *M. Lenné* and *M. Soelaegiana nigrâ*, coloured plates have been published in the *Garden*. *M. Soelaegiana* has flowers similar in shape and size to those of typical *M. conspicua*, but they are deeply tinged with red; *M. Soelaegiana nigrâ* has dark plum-coloured flowers. Both these bloom a week or ten days later than the type. Other seedling forms or slight varieties of the Yulan are *M. Alexandrius*, *M. cyathiformis*, *M. speciosa*, *M. spectabilis*, *M. sepeha*, *M. triumphans* and *M. Yulan grandis*.

M. FLASERI, a native of the Southern United States, is easily recognised by its light-green

OF ILLINOIS AT URBANA-CHAMPAIGN

M. HYPOLEUCA.—So far as we have been able to ascertain, the only figure of this beautiful species (excepting one in a Japanese publication which is not easily accessible) is in *Garden and Forest*, Vol. I, p. 303. From an economic standpoint *M. hypoleuca* is perhaps the most important of all the *M. gracilis*; the wood is straight grained, easily worked, and dull yellow-grey in colour. It is the wood commonly used by the Japanese in the manufacture of objects to be lacquered; it is preferred for sword sheaths, and the charcoal made from it is used for polishing lac. In the southern part of Yesso it is abundant in the

Coombe Wood Nurseries, and will doubtless become as great a favourite as the type. Both are dwarf-growing deciduous shrubs.

M. TRIPETALA, a native of the Southern United States, has large, slightly scented, white flowers, from 5 inches to 8 inches across, and obovate-lanceolate leaves from 1 foot to 3 feet in length; in a wild state the tree rarely exceeds 40 feet in height. Philip Miller was the first to introduce this fine species to British gardens. Other names for it are *M. Umbrella* and *M. frondosa*.

M. WATSONI.—A coloured plate of this very beautiful Japanese species was published in the *Garden* in December, 1883, under the name of

Cauliflower "Autumn Giant."

forest and forms fine trees 60 feet or more in height, with a trunk diameter of 2 feet. The leaves are broadly obovate, a foot or more long and 6 inches or 7 inches wide, dark green and smooth above, and clothed with white hairs beneath. The flowers are creamy-white in colour, deliciously fragrant, and when fully expanded measure 6 inches or 7 inches across, the brilliant scarlet filaments forming a striking contrast to the petals. There are no large specimens as yet in this country, but as the species thrives well in the North-eastern United States, it is fair to assume that it will do well in Britain.

M. KOBUS, a Japanese species grown in the United States under the name of *M. Thunbergii*, is as yet very uncommon in this country, and we have not yet seen it in flower. In habit it seems to approach dwarf-growing forms of *M. conspicua*.

M. MACROPHYLLA.—This, unfortunately somewhat tender in a young state, is worth growing simply for its beautiful leaves, which are green above and clothed with white hairs beneath; they attain a length of upwards of 3 feet. The open bell-shaped fragrant flowers are white with a purple blotch at the base of the inner petals and measure 8 inches or 10 inches across. In its native habitats, the Southern United States, it forms a tree from 20 feet to 40 feet in height, with a trunk rarely exceeding a foot in diameter.

M. OBOVATA (see illustration on p. 419) is a native of China; in Japan it only occurs in cultivation. It is a dwarf-growing bush, perfectly hardy in the South of England, and bears freely its purple, sweet-scented flowers, though not in the same profusion as are those of the white-flowered *M. conspicua*. This species has a number of synonyms. Amongst these are the following, which are the most frequently met with in books and nursery catalogues: *M. discolor*, *M. denudata*, *M. liliflora*, *M. purpurea*, *Talauma Sieboldii*, &c. There are several varieties, but these differ so slightly from each other and from the type, that descriptions without good-coloured figures would be next to useless. The best are *Borrei*, *angustifolia*, and *erubescens*.

M. STELLATA.—An excellent-coloured plate of this very beautiful Japanese shrub was published in the *Garden* in June, 1878, under the name of *M. Halleana*. This species is the earliest of the *Magnolia* to flower, and it should be extensively grown for the beauty of its starry white flowers. A variety with bluish-coloured flowers sent from Japan by Mr. Marice has not yet been seen, but by Messrs. Veitch, but it grows freely in the

M. parviflora; at that time it had not flowered in British gardens. It is quite hardy. It has large, creamy-white, fragrant flowers, with petals of great substance and deep red filaments, which add materially to the beauty of the blossoms. The true *M. parviflora* is probably not in cultivation in Britain. N.

4577.—*Clematis* for a trellis.—I do not think you can improve upon *Clematis Jackmani*; it is by far the most attractive of all the species, and if you commence with a good stout plant will cover the trellis rapidly.—A. G. BUTLER.

—The best *Clematis* for the purpose of covering an arch or trellis is *Jackmani*; Snow-white might be associated with it. General Jacquemont is a good dark H. P. Rose and forces well under glass: W. F. Bennett (hybrid Tea) would also probably suit. Then if a very free grower was required try *Reine Marie Henriette*, the *Red Gloire de Dijon*.—E. H.

—*Clematis Jackmani* is the best for covering a trellis or arch. If you want variety it is possible that *Clematis Prince of Wales* would thrive, as it is a strong grower and flowers freely. You must move up the soil to a depth of 18 inches, and mix some rotten manure with it. *Reine Marie Henriette* is a good red Rose for a cold-house. If you want one of a darker shade of colour you may select *General Jacquemont*.—J. C. C.

—I can advise no better kind for this than the large purple-flowered *C. Jackmani*, or one of the varieties which have been recently described in *GARDENING*. This free kind will do as well for the trellis or for the arch over the path, producing its rich masses of large deep-purple flowers throughout the summer. *Cheahunt Hybrid* would be a good Rose for this purpose. It is a showy kind, blooms freely, and its flowers are of a deep-crimson colour, whilst they are very fragrant. Both climbers may be planted now, and prepare the soil well in the first place.—C. T.

—*C. Jackmani* is far away the best variety to plant for covering a large space in the shortest time on any aspect. The flowers are most freely produced from the early part of July till the middle of September, if the roots are regularly supplied with moisture. The colour is a deep violet-purple, extremely showy. To grow *Clematis* really well the varieties require special pruning. For instance, *Jackmani*, which produces its blossoms on the current year's shoots, needs close pruning to induce a vigorous summer growth to be made. The first week in February prune the shoots of last year's growth back (to within an eye or two of the base, where growth started. If a light-coloured variety is preferred,

Albert Victor (deep-lavender, with pale bars) or *Sir Garnet Wolseley* (pale-blue, with plum-rod bars) are to be recommended. Both these flower on the last year's wood, and therefore need but little pruning, just removing the points of the shoots where rather weakly. By the addition of partly-decayed manure the poor soil may be improved, and by a regular supply of moisture, both at the roots and over the foliage, success is easily achieved. *Reine Marie Henriette* is the best dark-red climbing Rose. This is sometimes called the *Red Gloire de Dijon*. In the bud and half-opened stage this is a charming variety.—S. P.

4556.—*Evergreen creepers*.—It is by no means an easy matter to secure six sorts of evergreen plants that will grow 30 feet high and flower also. For instance, *Clematis* and *Roses* might be employed, but they are not evergreen. The following are the most suitable: *Ceanothus divaricatus*, pale-blue flowers, produced in quantity during May—this grows very fast if treated liberally; *Pyraeantha crataegus*, (commonly called the *Fire Thorn*), this grows rapidly; the flowers are borne in profusion during the summer, followed by a full crop of richly coloured berries, which hang on all the winter if the birds are not allowed to eat them. *Garrya elliptica* produces its catkin-like blossoms during the dull days of November, therefore is worthy of a place. *Lonicera aurea reticulata* has golden-coloured foliage and white blossoms, which are very sweet, and flowers almost the whole of the summer. This is perhaps the fastest growing creeper we have. *Lonicera brachypoda* is another form of *Honeysuckle* with pinky white blossoms, exceedingly sweet. *Choisya ternata* (commonly known as the Mexican Orange-tree) grows moderately fast and flowers so profusely that it ought not to be left out of even a list of six climbers. The end of March will be the best time to plant, as nurserymen supply all of these in pots, they can then be easily shifted, without fear of a check to growth. Any ordinary garden soil not less than 2 feet deep will suffice if partly rotted manure is added liberally at planting-time. Abundance of water should be given during a dry summer and the foliage ought to be well syringed occasionally.—S. P.

THE KITCHEN GARDEN.

VEITCH'S AUTUMN GIANT CAULIFLOWER.

THE value of this Cauliflower when sown early in spring for use during September, October, and November cannot be overestimated; neither does it need any praise from me to extend its culture, for this is well-nigh universal. My object in referring to it now is to point out its value as a summer Cauliflower for use from the middle of July until the spring-raised plants turn in. I have for the past few weeks been cutting heads of this Cauliflower faultless in every respect, being solid, heavy, and white, and I can safely say I know of no other variety that will produce equal results. With the accommodation of glass, which in most places has been extended of late, there has been a tendency on the part of some gardeners to give up autumn-sown Cauliflowers and depend upon those raised under glass in spring and also using earlier varieties; but if the ground is not extra good these very early sorts do not come large enough to make solid heads, so as to compare favourably with the autumn-sown stock. I would strongly advise these who have not yet tried *Veitch's Autumn Giant* when sown from the 10th to the 20th of August, and again a week later, to do so. This ensures there being one batch at least in a suitable state to prick out into hand-lights to stand the winter, where they should be treated as the other varieties, such as *Early London*, to which they will form a capital accession. C.

GROWING TOMATOES.

Now that this favourite crop is about over, a few lines on the ways of growing may not be out of place, although you would think, by so much being written about which is the best way to get a good crop, the subject would have been exhausted long ago. Yet I am convinced, after two years' trial, which mode is best. My Tomatoes had a span-roof running

north and south, 40 feet long by 22 feet wide, heated just to keep frost out. This year my plants were planted out with the first fruits set in rows 2 feet apart by 1 foot in the row. They were planted in a good loam soil, intermixed with road scrapings to keep it light. When all were planted I staked them nicely with slater's laths, 7 feet or 8 feet high, and very neat and trim they looked, and I never saw plants more like doing well. In about three weeks the house was a perfect wood; they had grown 2 feet in that time—in fact, too fast, as gross and strong as possible to be, but not a fruit set. However, they did well when they had had their run awhile, and I got about 650 lb. of fruit off 120 plants. To come to the point, I was convinced, after seeing another house about three miles away, that I was ignorant of Tomato-growing. Now to describe the other house, something similar in size, but not so high as mine, planted in rows in Orange boxes, and here's where, in my opinion, the secret is. When I saw this house it was a perfect sight, and the crop would average quite a stone a plant. They were set out, he said, just nice plants, about a foot high, just sufficient soil to start them, and then continual top-dressing. This, anyone will see, is to prevent gross and rampant growth; when they showed signs of exhaustion they were fed with sheep-manure-water. To those who are not satisfied with their mode of culture, I would advise the following rules: 1, Plant in a bed of a decent size, a foot or so square; 2, Top-dress well, and often; 3, tie up and pay attention to offshoots and leave at least once a week; 4, Feed well with some good stimulant when wanted; 5, Get a good sort, and keep it, and never plant more than one sort in a house; 6, The last, but failing it success is out of the question—sir. Few people, especially amateurs, know what air is to Tomatoes, and, indeed, all other plants. Anybody that observes these rules cannot fail in growing Tomatoes. I may say in conclusion that the kind I grow is a good variety of Prelude. Someone will say, I know, it is not a weigher, but what it lacks in that point it gains in others—viz., a sure and heavy crop, beautiful fruit, which gains 3d. a pound more than any other variety I can grow.

J. G. PETTINGER, Harrogate.

ORCHIDS

DENDROBIUM PIERARDI.

This species, by reason of its easy culture, profuse flowering, and cheapness, is one of the best Dendrobiums for general cultivation. It was introduced to the Calcutta Botanic Garden by Pierard at the beginning of this century, and not long afterwards was sent over to England. It appears to have been the first of the Indian Dendrobos that flowered in this country, this event occurring at Kew. It is found in great abundance in a wild state, and its natural range extends over a very wide territory. According to Sir Joseph Hooker, it is very frequently met with in the hot valleys of the lower Sikkim Himalayas, where it grows on the trunks of fallen trees. Thence, it spreads southwards to British Burmah and Moulmein. It has slender pendulous stems, which in this country usually measure from 2 feet to 4 feet long; but in the Botanic Garden at Calcutta, where it is cultivated by being fastened on the branch of a tree, and its roots kept continually moist by artificial means, they reach a length of 6 feet. It is the general practice to grow this plant in baskets suspended near the glass, a method which allows the long-flowering stems to be seen to great advantage. In low houses, however, this plan is often inconvenient, and the stems have to be trained erect, as has been done with the admirably grown and flowered specimen illustrated. The flowers, which are usually at their best in March, are borne on the stems of the preceding year's growth, being produced singly or in pairs at each of the joints on the upper two-thirds of the stem. Each flower is from 1½ inches to 2 inches across, or it may be a little over in the best varieties or unusually strong plants. The sepals and petals are of a pale mauve, tinged with rose; the lip is broad and flat, and of a soft primrose-yellow, marked with purple streaks at the base. The delicate contrast between the lip and the other segments, and the soft tints of the whole flower, make this one of the most charming of the

drobes. As in all Orchids that are spread over a wide area, considerable variation is manifested in the size and shape of the flowers, some having more pointed sepals and petals, and others a broader lip.

THE CULTIVATION OF *D. Pierardi* is the same as for *D. uobile*. I prefer to grow it in teak-baskets, the compost consisting of peat-fibre (from which all earthy matter has been removed) clean Sphagnum Moss, and lumps of charcoal. From the time the new growths begin to appear until the end of September, a stove temperature and a saturated atmosphere should be maintained, water, of course, being freely supplied. After the leaves show signs of decay, the moisture should be gradually reduced until in winter no more than is sufficient to prevent the shrinking of the stems should be given. From October to February the plants should be in a comparatively dry position in a cooler house. It will be noticed from the absence of non-flowering stems that the specimen from which the illustration was made has been grown on the pruning system, and it undoubtedly stands as a powerful argument in its support. Some years ago a good deal of controversy arose as to the merits of this practice, which consists in removing the stems that have flowered and are, therefore, of no further value in that respect. Of course, with species like *D. Pierardi*, which flower on the growths last made, it would not do to cut off these until the new ones that spring from them had almost or quite completed their growth. Although from the physiological standpoint the practice is wrong, robbing, as it does, the new stems of

the year—they are not, or should not be, subjected to anything like the exhausting conditions which attend their growth in Nature; consequently the need of a reserve supply is proportionately reduced. This, no doubt, explains to some extent the comparative indifference of some Dendrobiums to the absence of old stems. Plants grown on the pruning system require a higher temperature and a moister atmosphere than unpruned ones do. I advise all who contemplate adopting this practice to do so at first in a tentative manner. For myself I confess to a preference for the older system. W.

DENDROBIUM BIGIBBUM.

I AM FAVOURED with a fine spike of this plant from "C. H. F.," asking if it is *D. Phalaenopsis*. He says it comes from the Island of New Guinea, and he hopes it is that species. Well, it is not *D. Phalaenopsis*, but the plant named above, and an excellent variety of it. One mark in particular by which this species may be defined from *D. Phalaenopsis* is by the presence of a white patch on the disc of the lip. This is composed of some pure-white papillæ, which are invariably present, but I have never seen it present in flowers of *D. Phalaenopsis*, although I have seen hosts of flowers brought from its native country, as well as those grown at home. I have frequently seen plants of *D. bigibbum* which have been brought from various islands in Torres Straits, but I do not know that I ever saw a plant from New Guinea, and I had

thought these plants appeared to be freer in their growth and better doers than the plants which I originally knew the species by, and which were said to be from the extreme northern part of the mainland of Australia. The young growths of this species retain their leaves until about two years old, and the racemes of flowers proceed from the top of the bulb and from the side buds near the top, continuing to push out fresh spikes from the old stems for years oftentimes; so that it is bad policy to cut away the old stems. These racemes last a very long time, so that the species will continue to supply a continuance of flowers for personal decoration for a very long time, whilst by growing a few plants of the same kind a long succession may be maintained. *D. bigibbum* and *D. Phalaenopsis* require a great heat to grow them well, and they should be liberally supplied with water during the summer months, which is their growing season, both to their roots and in the atmosphere, so that good drainage is indispensable to them; but during the winter far less is requisite—in fact, just enough to keep them in a plump condition without, but if it is considered desirable to reserve their leaves, do not thoroughly dry them off.

MATT. BRAMBLE.

Dendrobium Pierardi.

the fool stored away in the old ones, its supporters have the strong argument that plants have been grown as vigorous and as well-flowered as those not so treated, a fact which those who have attended the exhibitions and meetings of the Royal Horticultural Society have seen for themselves. The reservoirs of food—as the old stems really are—have been evolved in a state of Nature to enable the plants to survive long and severe periods of drought. Under cultivation—although it is necessary, as I have already pointed out, to keep the plants almost entirely without water at one stage of

CYPRIPEDIUM PARISHI, ETC.

I HAVE NOW to deal with a subject which I should not have thought came within the cognisance of a reader of GARDENING, but I heard a remark the other day that one never knew their luck, and this question has come as a surprise to me. "Walter Ramsbottom" asks if I can tell him something about *C. Parishii* and some other of the East Indian long-tailed Slipper Orchid? He is wishing to grow them, and he asks if there is any reason why he should not? To this last part of the

question I can only answer, No, there is no reason why; and I should have advised "W. R." against going into the cultivation of these plants because of the expense in these days of coal strikes, but my correspondent cuts me short by saying, "I am quite independent of coal or coke, having got a splendid little oil-stove fixed, which costs next to nothing," so I have nothing to do but to commence, and I do so with the species I am asked about.

C. PARISI.—This is a plant which I have known for some years, it having been introduced in the first place by the Messrs. Low, of Clifton, some twenty-five years ago. It is a plant of robust growth, and its scape bears four and five flowers of good size, the petals being spirally twisted, and of a glossy purple, with a few blackish spots towards the base. The other parts of the flower are green or greenish-yellow, which detracts somewhat from its effect, and I look upon this plant as of more importance to the cultivator at home as a hybridiser than anything else.

C. PHILIPPENSE is another of these Eastern species, and very beautiful it is. It was first discovered by Mr. John Veitch, when collecting in the islands of the Indian Seas, and was long known in our gardens as *C. levigatum*, and it brought very long prices, as much as twenty and thirty-five guineas being asked for small plants with a single growth; but now it is very much cheaper. The petals are spirally twisted; they are yellowish-green at the base, where they are fringed with short hairs, passing into a reddish-brown; they are between 5 inches and 6 inches long, the dorsal sepal white, striped with purple, and the pouch or lip tawny-yellow, with some darker veins. A plant very similar to this has been introduced by Mr. Sander, which he calls *Roebeleni*, and which some authorities, I see, make it to be the same species.

C. ROTHSCHILDIANUM is a beautiful kind, and the plant called *Elliotianum* appears to be the same species. The dorsal sepal and lower sepal are white, or creamy-white, with dark bands the petals are long, standing at right angles, striped in a similar manner; the lip is of a dullish-brown. It is a beautiful plant, carrying four or five of its large flowers all expanded at the same time. Both these plants were introduced by Mr. Sander, of St. Alban's, to whom we are indebted for so many of our fine Orchids.

C. STONEL.—This is always a fine plant, which was introduced by the late Mr. Stuart Low some thirty-three years ago, and it always will be regarded as a gem. The dorsal sepal is white, or with a few black stripes, the petals being some 5 inches or more long, slightly twisted; they are pale-yellow at the base, spotted with crimson, their ends wholly of a brownish hue, the lips of a brownish hue netted with crimson veins. I may as well mention the variety *S. platynebotom* here, although I am afraid my friend "W. R." will be a long time ere he gets it. This plant, like the species, was introduced by Mr. Low, and it passed into Mr. John Day's celebrated collection at Tottenham, but at his decease most of the plants went into the hands of Baron Schröder and Sir Trevor Lawrence, and they have increased considerably in value; but it is a superb plant, having the sepals the same as the type, but the sepals are very broad, being just upon an inch wide, and coloured of a creamy-white, spotted with crimson, the tips wholly crimson. C. Low must be included amongst the long-petalled kinds. It grows naturally on trees. It is a very showy species, having the petals about 3 inches long, broadest at the tips, where they are of a rich violet-purple, the upper part greenish-yellow spotted with deep purple, the lip being greenish-purple. **C. Haynaldianum** is a very similar plant, but the petals are not quite so long. They are greenish-yellow at the base, spotted with brown, the ends being dull purple, as also is the lip. I conclude the enumeration of the long-tailed Eastern species of this genus with the wonderful plant called *C. Sanderianum*, which is a very handsome kind, and has petals

which are narrow and reach the length of twenty-six inches. The flowers are hairy on the outer side, the sepals, yellowish, tinged with green, having broad blackish stripes, the petals narrow, slightly twisted, yellow at the base, becoming dull purple for about twenty inches, spotted with yellow and brownish purple. It is a wonderful plant which I saw flowering and doing well in Mr. Tantz's collection the last time I visited it when at Shepherd's Bush, and it has, I believe, furnished his gardener with pollen for hybridising. Now I must say a few words about the culture of these plants before leaving them. They like to be set in the warmest place possible,

Summer use of Seakale pots in flower garden at Woodlands, Cobham.

and they like to stand near the glass, but not exposed to all the sun's rays, but yet they do like the sun to shine upon them, and they also like a good moist atmosphere. They should be well supplied with drainage, as they like a good supply of water to their roots. Pot in good peat-fibre and Sphagnum Moss; during the winter season much less water is necessary, both in the atmosphere and to their roots, but do not allow them to suffer from want of moisture at any time of the year.

MATT. BRAMBLE.

TRICHOPILIAS.

I AM induced to offer a few remarks upon these plants from receiving a note from a lady in the Emerald Isle, "Miss Carey" by name, who sends me a flower of the good old Mexican species, *T. tortillia*. Now this is a plant that was first introduced nearly sixty years ago, and the plant has never been lost since. There are two varieties of the species, or the same plant produces two crops of blooms in one season. The flowers are large, the sepals and petals are spirally twisted, brownish-purple in the middle, bordered with white. The trumpet-shaped lip is ivory-white, spotted and dotted with rose and brown.

T. COCCINEA is a plant resembling the former one in its growth, but the bulbs are slightly longer. The flowers are, however, of quite a different hue, being long, with a wide trumpet-shaped lip, and of a deep but bright-crimson. It comes from Central America.

T. MARGINATA—This is a beautiful large-flowered and bright-coloured plant. It usually bears two or three flowers together upon one stalk. These are the same shape as those already noticed, and they are rich-carmine. This plant is a very free bloomer. I have frequently seen the same plant produce a double crop of bloom in the one season. It is now more than forty years ago since this plant was sent to us from Central America by the Polish collector, Warszewicz, who is said to have discovered it on the Central Mountains at a considerable elevation.

V. CALCOTTIANA.—This is the plant which was figured in the "Botanical Magazine" in 1865 as *T. Turlivae*, after the name of the great white mountain upon which it was found; but the plant had been found some twenty years before this figure appeared by Calceote and named after him. The flowers are of good size, of a yellowish white, the lips being of a deeper yellow spotted with red.

T. SUAVIS.—I have left this fine species with its variety *alba* until the last, and I would earnestly beg "Miss Carey" to invest in this, for its flowers are large, beautifully coloured, and with a delightful perfume resembling May blossom. It bears several flowers upon one peduncle, the sepals and petals being creamy white, the large lip being beautifully fringed, and spotted with rosy-pink. In the variety *alba* the flowers are pure white, saving the deep yellow which is to be found in the throat; but the rosy-pink spots and blotches are quite absent, but it has the same delightful odour. The above are some of the principal kinds known in this little family, but all are well worth my correspondent's care; they are plants which do not require much care, but they do require good drainage to maintain them in good condition. They require good peat-fibre and Sphagnum Moss to grow in, this to be pretty well elevated above the pot's rim, because the flowers are produced under the leaves, and there is not room for them to display their beauties if this is not given attention. They are plants which like a good supply of water during the growing season and when they are flowering, and at this time it is well to plunge the pots in a pan or tub of water, but not so deep as to wet the flowers, and after the flowers are gone the plants should then be plunged over the growths and be allowed to soak well. This will compensate for any dryness which may have overtaken the bulbs through being set higher up than usual above their surroundings; but do not allow the plants to get thoroughly dry. At any time in the year the plants can be thoroughly rested by keeping them drier and placing them in a cooler position. The majority of the plants named above succeed well enough in the *Odontoglossum*-house, but I would prefer the warmest end of such a structure for them, and I would give them the opportunity of getting more sunshine than the *Odontoglossum*, which require more shade. But I consider that the greatest ruin occurred in the early days with *T. suavis* through keeping it too hot. The leaves became shrivelled and turned yellow, the bulbs shrivelled up and wasted away from keeping them in the Cattleya-house all the season, when they would have plumped out their bulbs, and their leaves have been more of the consistency of stout leather aprons if kept in the cool-house. MATT. BRAMBLE.

SUMMER USE OF SEAKALE POTS.

WE were pleased last year in Mrs. Earle's garden, Woodlands, Cobham, to see how prettily these were used for half-hardy plants in summer, as shown in our engraving. The pots were simply turned up, roughly drained, filled with Scarlet Pelargoniums and other half-hardy plants, and placed on a little terrace, where they looked very well. The pot is really better in form than the usual garden pots.

A new Pompon Dahlia.—By far the most brilliantly coloured variety in this useful class (or, indeed, in any other as far as I know). It is a new one called Sunshine. It produces rather large but perfectly formed blossoms of the most dazzling vermilion-crimson that can be imagined on a very dwarf and bushy plant. This fine variety, which will prove a gem for cutting, is quite distinct from the old one of this name, and a great improvement on it also.—B. C. R.

4576.—Flants and insects.—Your query is very indefinite. Send a few of the insects and one may tell better what course to advise. The only way we should think is to search for them, especially if they are slugs, snails, or similar marauders. Insects that infest plants are many in number, but we should think the mischief is done by the caterpillar. Search for them, and in the evening or early morning is the best time to do this.—C. T.

Measure with root and stem liberally next winter

HOUSE & WINDOW GARDENING.

EVERGREEN CREEPERS FOR A SOUTH HOUSE WALL.

4556.—The following list of creepers suitable for the south side of a house may be found useful, but "John" does not mention the locality or soil, and also whether the position of the house is much exposed to high winds. If in the northern counties, or in a very cold situation, it would be best to grow some of the handsome varieties of Ivy instead of the more delicate creepers here mentioned. Magnolia, for instance, though perhaps the queen of climbers in Devonshire and other southern counties, would not do so well, perhaps, in the north of England. Evergreen Honeysuckle (*Lonicera sempervirens*, with its varieties *L. brachypoda* and *L. aureo-reticulata*), should be included for its quick growth and delicious scent, the two first named being specially floriferous, while the Golden Honeysuckle (*L. aureo-reticulata*) is of lower growth, and is a shy bloomer, although the foliage is variegated and handsome, making a good variety. Of Evergreen *Rosa* the two best are *Félicité Perpétuelle* and *Princesse Marie*, but the fine old *Gloire de Dijon* Rose is so nearly evergreen and so well worth having for its mass of lovely blossoms that it should certainly be planted. The *Ceanothus* family gives us some of our finest climbing shrubs, but some are more hardy than others, and of these *C. azaricus* is perhaps the most satisfactory. The foliage is always handsome, and although the azure-blue flowers are individually small, they are produced in such extraordinary profusion during the whole of the summer that the effect is of a perfect mass of bloom. *Ceanothus americanus* is also fairly hardy, bringing quantities of pure white blossoms from June to August, while *C. Veitchianus* is perhaps the most beautiful of all, the flowers being of a deeper azure, and borne in masses at the top of each spray of leaves. All the *Ceanothus* family need rather dry, gravelly soil with good drainage, and they flower where the wood is thoroughly ripened by strong sunshine. They should be pruned each year about the end of April, and as they bear all their flowers on the wood of the current year, they may be sharply cut back when necessary. *Mahonia nepalensis* is a remarkably fine climber in Devonshire, but would not be perfectly hardy probably in colder localities. It is a *Burberry* with extraordinary leaves of about eighteen inches long, and large clusters of golden flowers in the spring. The more hardy *Mahonia* (*Berberis*) *Aquifolium*, makes a fine climber to cover the lower part of a house, its beautiful shining leaves, which turn scarlet in the winter, bunches of rich-purple berries (also borne in winter), and the pretty yellow sprays of bloom which are produced in early spring, make it most desirable and attractive as a wall climber. *Garrya elliptica* is a handsome evergreen climber, which is covered in winter with long tassel-like flowers of great beauty, giving the effect of a draping of lace. In this plant the male and female flowers are borne on separate individuals, the tassels of the male plant being the most handsome, but those of the female being sometimes followed by dark purplish berries. It is best to grow a plant of each sex, if these are to be produced, and both the *Garryas* need deep rich soil. *Escallonia maorantha* is very lovely, with dark climbing foliage and a mass of rose-pink blossoms. This is quite hardy in the south, and would probably do well on a sheltered south wall in most parts of England. *Passiflora corulea* (the common Passion-flower) must not be omitted from this list. There is no more beautiful creeper when well grown, its long sprays of elegant foliage and delicately-tinted flowers are unique in their own way. Of the *Jasmines*, *Jasminum resolutum* is the only variety which retains its leaves in winter. It should be grown, if possible, but is not a common plant to procure. *Crataegus pyracantha*, with bunches of intense-scarlet berries in winter, is a very fine plant, and the decorative effect of its berries is wonderful. *Cotoneaster microphylla* makes an excellent wall plant, very handsome throughout the winter months with its profusion of osmine berries at every point. Myrtles, and other less hardy plants, may be added to the list for the south, but would not do so well in a cold

situation, and should certainly receive the shelter of a mat in severe weather. All these plants will be the better for well-prepared and deeply-dug soil, whether put in during the autumn months or in the spring, as this should be done at once, a trench of 2 feet in depth and the same in breadth being cleared of the old soil (unless it be in excellent condition), and filled with good loam or turfy-loam from an old pasture, with a liberal mulch of stable-manure on the surface after the plants are put in. This will help to keep their tender roots from the frost and enable them to make a fine start in the spring. Without it they would be in danger of perishing before their roots have taken firm hold of the soil, and in the case of the more delicate plants it will be well to wait until the severe frosts are over, planting in April, with plenty of water, and giving a mulch of old stable stuff over the roots, so that they may not be injured by the hot sunshine. A little care in planting, procuring good plants and spreading out their roots in a fan-shape (not dropping them into a perpendicular hole), will be well repaid in the future. I. L. R.

DAFFODILS FOR A ROOM.

The term "Daffodil" now includes not only the old favourite *Lent Lily*, but also the whole *Narcissus* tribe, with *Jonquils* also, so that a wide selection may be made of these fragrant flowers, which are especially decorative, too, with their soft tints of yellow, creamy-white, and touches of scarlet. The earliest-flowering section includes most of the *Polyanthus-Narcissus*, of which the double *Romun* and the *Paper-white grandiflora* are the best for forcing, and may be had, with early potting and no more heat than a sunny window affords, in full beauty at Christmas-time. *Narcissus Tazetta*, the *Joan-flower* of China (often called the *Fairy Lily*, or the Chinese Sacred Lily, though it has nothing

Next to these in opening their blooms are the sweet-scented *Jonquils*, both double and single, and these are followed by the beautiful *White Narcissus*, *White Pearl*, and many other varieties. Later in the spring the *Daffodils* proper—i.e., the yellow flowers which have always borne that name—open their blossoms, and many of these are now most magnificent. *Narcissus Ard-Righ*, *N. Horsfield*, *N. Emperor*, *N. maximus*, *N. obvallaris*, and *N. Barri* conspicuous, are some of the finest varieties of these, but there are many others of almost equal splendour. All these bulbs can be grown in pots, well drained, with a light compost, not too rich, and should be planted as soon as they are received from the horticulturists. The pots are best sunk in a bed of fine ashes out-of-doors, clearing away the ashes (which should cover the pots to the depth of 2 inches in winter), as the green of the bulbs makes its appearance, and top-dressing them with rich soil. They should be grown entirely out-of-doors until the buds appear (with the exception of the *Double Roman*, *Paper-white*, and *N. Tazetta*, all of which if potted early should be taken in before frosts occur), boxes of ashes on the leads, or a thick bed of ashes in a back yard, being the best places for the pots where grown in a town. The later and more hardy bulbs may, if preferred, be placed in the garden, and potted up in groups just as the buds begin to open. This is an easy and excellent plan where decorative plants are needed in the country, as the *Daffodils* are usually strong and hardy when grown in this way. *Orange Phoenix Narcissus* thus treated is very beautiful, being double and of specially rich and soft colouring. *Sulphur Phoenix* is also a charming pale-tinted variety well worth cultivation. "Sir Watkin" (here figured) is a very fine one. I. L. R.

4573. — *Azalea in a window.* — All *Azaleas* should be taken inside at night now, though they might benefit from exposure on

OUR READERS' ILLUSTRATIONS: "Narcissus 'Sir Watkin.'" Engraved for GARDENING ILLUSTRATED from a photograph sent by Messrs. Pearson, Chiswell, Nottingham.

to do with the true *Liliums*), is also very early, flowering about seven weeks from the time it is planted, either in pots or in water. In a shallow ornamental bowl, where the bulbs can be surrounded with pebbles to keep them upright, and not more than half covered with rain-water, they make a lovely drawing room decoration, only requiring to be kept in the dark for ten days while they are forming their first roots, and sheltered from sharp draughts when in growth.

fine, mild days. The most important matter in the culture of *Azaleas* is the watering. Too much or too little destroys the vitality of the plants. If any doubt exists about the plants requiring water, tap the pot with the knuckle; the sound will tell if the plant is dry or wet. Try its weight by lifting it up in the hand, and water or not as the plant is heavy or light. All that is necessary for *Azaleas* is to keep them safe from frost in a light room. *Azaleas* are much

hardier than many imagine. It was not uncommon years ago to find beds of Indian Azaleas growing outside in many sheltered gardens. Still, with plants in pots, exposure to frost sometimes injures the blossom-buds before they open, and it is best avoided.—E. H.

— I suppose you mean one of the ordinary Ghent Azaleas, if so by all means take it in on the appearance of frost, otherwise the buds will be killed. It is not easy to grow Azaleas in a room, the buds dropping through the dryness of the atmosphere, change of temperature, and other details. The only thing is not to keep the plant in a gas-lighted room, and syringe the foliage occasionally to remove accumulations of dust or dirt, which, however careful one may be, will settle on the leafage. Another thing is to regulate the watering with the utmost care, giving only sufficient to moisten the soil and no more. Do not let water remain in the saucer, but drain it off directly after the plant has been watered. A gas-lighted room is very troublesome. The air gets so dry and hot, and materially affects the plant.—C. T.

— You should take this inside before frosty weather sets in. But as you could hardly have chosen a worse subject for window culture, and are almost certain to be disappointed with the results, I would strongly advise you to make an exchange with some friend who has a small conservatory or greenhouse.—P. U.

FERNS.

4580.—**A Fern case.**—No plants will grow and keep in health long without drainage. Have some holes drilled through the bottom or ends of the case so that the surplus water can get away. You might have a hole drilled close to the bottom at one end, fitted with a small tap, or even a tight-fitting cork would do. There is no difficulty attached to the culture of Ferns in such cases.—E. H.

— These are often made without drainage holes, in order, I fancy, that no water may escape on to carpets, etc., when standing in a room; but I do not consider it is at all right, or as it should be. If the hole is made in one corner, it is easy to put a bucket or pan underneath when watering, and leave it until all surplus moisture has drained away. You did quite right to put a layer of cinders in the bottom, and peat, if mixed with plenty of sand is good material for most Ferns to grow in, but perhaps you did not make it sufficiently firm, or too much or too little water has been given. It is, in fact, difficult to say where the treatment has been wrong without either seeing the plants or knowing how they have been treated throughout. Too much moisture is quite as bad as too little, for it renders the soil sodden and sour, and then the plants cannot possibly thrive. I find a mixture of loam and peat better than pure peat for most Ferns, and a little lime is useful, as it tends to keep all sweet. Again, do not keep the case too close, especially in hot weather, but admit a little air, if possible at the top of the case rather than at the side, for two or three hours, morning and evening.—B. C. R.

— Evidently you have entirely mismanaged your Fern-cases, and unless there is a way of escape for the water given to the Ferns it is impossible for the growth to be healthy. The first thing to be done is either potting plants or putting them into boxes, as in this case, is to see that the drainage is thoroughly good and the reason is obvious. If a plant is in a water-logged soil it soon gets unhealthy, and the soil naturally becomes sour, the result being death of the Fern or whatever plant is used. First see that there are sufficient holes for the water to escape, and as regards the drainage, cinders, etc., you have acted rightly, and a peaty soil is most suitable for the Ferns. During the winter less water will be required than in the summer, and keep decaying fronds picked off, as these promote decay, and ultimately death ensues. The glass must be wiped out at frequent intervals to prevent damp, and the sun should not shine full upon it. There are a few general hints that may be useful to you.—C. T.

FRUIT.

4581.—**Planting Strawberries.**—Within the last half century the varieties of this fruit have been greatly increased in number. It is best to select the first runners for planting, and mark them by pegging them down. They will produce fruit next season; those which come from them probably not. It has been supposed that the runners exhaust the plant, and it has been advised to cut them off; but the result of experiment is that the produce is the same whether the runners are left or removed. The varieties called Alpine Strawberries bear colder, damper, and more shady situations and lighter soil than the others, which prefer a good mellow loam, even inclined to be clayey, such as would be suitable for Wheat. The alpsies bear late; their fruit is conical in shape and has a peculiar aromatic flavour, which is brought out by preserving in sugar. Of the old sorts the best are the Bath Scarlet, early, abundant bearer, much sought after for preserving; the Chili, large, round white, and a very useful Strawberry, though many find fault with it as not being sufficiently high flavoured; another variety, the Hautbois, of peculiar flavour, much esteemed by some, but not generally cultivated. Many of the plants are sterile males, and as they increase by runners even faster than the prolific or hermaphrodite plant, they must be carefully nipped as soon as discovered, otherwise the bed at the end of a short time will be overrun with unproductive vegetation. Amongst the celebrated modern kinds the Elton, raised by Knight, stands high; it is a late variety, large, cockscomb-shaped, abundant bearer, and should be suffered to ripen thoroughly before gathering. Keen's Seedling, very abundant bearer, early, well adapted for forcing, grown in immense quantities for the London markets, and excellent for main crops; the British Queen is probably the best late Strawberry. The Black Prince is one of the most prolific kinds and is very early. Soils make a wonderful difference in Strawberries; the very best is a sandy loam. In this they will not grow more to root and top than is necessary for the formation of good buds for the next year; while in a rich, light mould, if the autumn prove wet they will produce a large watery mass of tops, growing on to the middle of October, and producing no buds in the centre. I have practised the following plans on light soils. Where the Strawberries were planted out in poor sandy soils, I have obtained a famous crop by giving plenty of liquid-manure in spring. I have also planted the runners in small pots filled with loam, and about the 1st of November planted them out for the next year's crop. I never put more than one plant in a pot 8 inches deep, 1 foot in the row, and 2 feet asunder. By this means a good crop will be insured, and mulching between the rows with fresh stable-manure about an inch thick all over the ground just as the Strawberries are coming into flower. If the weather be dry water should be given several times; this carries the strength of the manure down to the roots, and by the time the fruit ripens the straw will be clean and free from smell.—T. W. P.

4547.—**Thrips on Vines.**—You should take the Fuchsias out of the house at once and deal with them outside. Thrips on Vines are dangerous, as they eat the green matter from the leaves, and may not only injure the present crops but have a deteriorating influence upon next year's crops. Fumigations with Tobacco on successive evenings will destroy thrips; but if the Grapes are ripe the Tobacco-smoke will injure the flavour. On the whole, the best way of dealing with thrips on Vines is to sponge the leaves on which the insects are with a strong solution of Gishurst Compound; but in bad cases of thrip the insects descend into the bunches and eat the bark round the berries, and then there is nothing for it but to fumigate moderately on several successive evenings, ventilating freely during the operation so that the Tobacco fumes may pass away.—E. H.

4538.—**Bottling Grapes.**—A great deal depends upon how the Grapes are ripened. If thoroughly ripe when out Lady Downes will remain quite fresh in bottles of water for six months. A suitable room is necessary—one that can be darkened, and kept cool—say temperature not below 33 degs. nor above

45 degs. during the winter. What is required is a cool, dry air; any sign of dampness in the air would be detrimental to the berries, and if one of these exhibit the slightest sign of decay it should be cut out at once, as it would contaminate the rest. Grapes that are required for use after November are usually bottled, as after that time it is not good for the Vines to allow the Grapes to hang on them. It is not necessary to bottle any required for use before that date; it is usual to let them hang on the Vines, but should they be in the way of plants or anything else in the house they can be cut and bottled with success. Ordinary wine-bottles will suffice. These can easily be hung up to a nail in the rafters of the roof or elsewhere, or a temporary rack can be made which will admit of the bottles swinging. If a piece of wire is fastened round the neck of the bottle, filled with clean water, the weight of the bunch will balance the bottle when hung up, and in this way the Grapes will hang clear of the bottle. Three inches to six inches of stem should be allowed to each shoot below the bunch, according to the distance of the bunch from the main rod. In cutting the stem upon which the bunch is borne, care should be taken not to interfere with the eyes nearest the stem of the Vine, as these are intended to be left in pruning to give the next season's crop of fruit. With the water should be added one teaspoonful of powdered charcoal, but not too fine. This will assist in keeping the water sweet for the bunches that are intended to hang the longest; but for hanging, say, a month or so, this is not necessary. Place the stalk in the bottle as deep in the water as is necessary to enable it to remain firm. The stems above the bunches should be left intact, as the berries are not then so liable to shrivel. After the bunches have been cut about two days more water must be added to that in the bottles, as the stems will have absorbed a quantity, and any of these which were short may be quite dry on account of the absorption.—S. P.

4563.—**Management of Pear-trees.**—There may be two reasons why the Pear-trees on the wall do not bear fruit. One may be owing to bad management; the other they may not be free-bearing sorts. Trees in the open garden will bear if they are simply let alone, but on a wall they require a system of pruning and training that will suppress the development of too much young wood, and that will promote the production of fruitful spurs. In rich soil Pear-trees will, if simply spurred back at the end of each season, do little more than produce a thicket of young wood from the old branches; whereas by careful summer pinching and pruning they will form fruitful wood in abundance.—J. D. E.

— "A. L." does not say if his trees make much growth or none at all hardly. Either of these failings would account for the thinness of the fruit crop. If numerous long eappy roots are made the trees require root-pruning; too much growth is being made. With a spade on a trench 3 feet away from the stem of each tree and as deep as roots are to be found. Just a narrow trench is all that is required, the object being to sever the large roots, which are devoid of fibrous matter, which really are the feeders of the tree, and not these long, fibreless roots. By cutting them in two numerous small roots will push from the extremity after the end of each has been clearly relieved of all jagged parts. Do not give such trees manure in any form until a full crop of fruit is borne, but keep the roots well supplied with moisture during dry weather. If the trees make but little or no growth at all, they ought to be lifted towards the end of October and replanted in fresh soil, thus encouraging new growth. Amulching of partly-decayed manure from the stables will not only feed the roots, but will conserve the moisture in the soil.—S. P.

The Dartmouth Crab.—What a beautiful subject this is, both while in bloom and when the fruit is ripe! The intense purple-crimson colour of the latter gives it quite the appearance of a tree of fine Plums, while the beautiful bloom on the fruit heightens the illusion—indeed, when walking through a large nursery in the neighbourhood recently with a friend he really mistook a plant of this Crab for a Plum and could scarcely be persuaded of his mistake. The Siberian Crab is a charming and much more familiar subject, but at least at this season it

Drawings for "Gardening."—Readers will kindly remember that we are glad to get specimens of beautiful or rare flowers and good fruits and vegetables for drawing. The drawings so made will be engraved in the best manner, and will appear in our issues in GARDENING ILLUSTRATED.

must yield to the former in attractiveness. These two Crahs, which (as well as a few others) thoroughly deserve to be freely planted in pleasure-grounds, are extremely hardy and easily cultivated, thriving excellently in cold, damp, or heavy soils.—B. C. R.

OUTDOOR PLANTS.

HARDY ANNUALS.

VIOLET CRESS (IONOPSIDIUM ACAULE).

This is one of the most charming little early spring annuals we possess. It had for many years been a general favorite for rockeries, and especially old crumbling walls, where it makes itself quite at home, and in a very few years takes full possession. It forms dense tufty rosettes from 1 inch to 2 inches high, with innumerable kidney-shaped leaves and abundance of pale violet flowers. It is a hardy annual in the true sense of the term, seedlings springing up in all directions where plants have seeded the previous year. As a weed in the rockery it is a very welcome one; the plants fill all the crevices and rarely get in the way of other dwarf growing alpine. It sows itself with such certainty as to possess all the advantages of a true perennial. Along rough stone-edged pathways, on rough stone steps, old brick walls, and leaved any receptacle that will give a plant a foothold, it may be grown with singular effect. The autumn-sown seeds produce plants which flower early in spring, and the plants from spring and early summer-sown seeds flower throughout summer and autumn. It is also largely used

a good time to put on the lime; but it would be a grave error to give the lawn a dressing of manure immediately after the lime. The better time to apply the manure would be in the spring—a month or so before commencing to cut the Grass; rake it well, and then roll it in.—J. D. B.

A dressing of lime and manure may probably benefit a newly-made lawn. A great deal depends upon its condition. Very often where the levels of the ground have been altered some of the inferior subsoil is brought to the surface; then a dressing of lime and manure is beneficial, but I have seen cases where the Grass grows strong enough without manure. Newly-slaked lime may be usefully applied to a great many lawns. Its tendency is to eradicate moss and banish worms, and it fines the Grasses. The best time to apply manure or lime, or both, is during the winter—say, December or January, so that the weather may disintegrate it, and render it fit to be absorbed. In February or March use the bush-barrow, or, if on a small sward, the rake or a herd, worn broom will do.—E. H.

A newly-made lawn should not require covering with either lime or manure, except where the Grass is weakly, then a thin dressing of decayed vegetable refuse and wood-ashes would be an advantage. If the ground is covered with Moss, a sprinkling of lime would tend to kill the Moss and thus allow the Grass a better chance to grow. Early in November is a good time to apply the top-dressing; by February it will have worked down into the soil, leaving nothing but stones or bits of wood.

almost useless, as well as undesirable, to attempt the culture of anything of either a strong-rooting nature or that requiring abundance of nutriment. Suitable plants for a wall with such an aspect are the Winter or Naked-flowered Jasmine, *J. revolutum*, *Escallonia macrantha*, and *Pyrus japonica*, or *P. Maniei*, or, if the wall is over 6 feet in height, a Passion-flower, a *Clematis* or two, and some *Roses* might be more suitable. In a warm, local climate the fragrant lemon-scented *Verbena* and *Myrtle* would probably survive the winter, and in a few years become very handsome plants, while, lastly, *Chrysanthemums* of the choicer varieties would thrive and bloom beautifully with care and plenty of nourishment. The border being full of the roots of the foregoing, the best kind of plants of low growth to be placed in front of them will be such as the *Thrifta* (*Armeria*), pink and white, *Sedums*, and *Saxifraga* of sorts, with a few *Petunias*, *Nolanas*, dwarf *Tropaeolums*, *Portulacae*, &c., in the summer time. A few plants of the golden variegated *Enonymus* towards the back would look nice. If *Chrysanthemums* were grown they should be well manured and frequently syringed in hot weather.—B. C. R.

You can hardly expect to do much laying out in a space 1 foot or 18 inches wide. You cannot do better than plant *Tee Roses* for covering the walls; the sorts may be *Madame Lemhard*, *Marie Van Houtte*, *Perle de Lyon*, and *Madame Eugene Verdier*. If you plant these *Roses* in 18 inches of good soil, you will get some beautiful flowers from early summer until late in the autumn; you may have two clumps of bulbs between each two *Roses*. These may consist of *Hyacinths*, *Tulips*, *Snowdrops*, and *Crocuses*, and *Daffodils* if room.—J. C. C.

"Soil" has a very small plot indeed to deal with, but as it is in a sunny position I would have a good display of bulbs in it, especially the early-flowering bulbous *Iris*, and the later Spanish and English varieties in great variety. The early species are *I. reticulata*, followed by *I. persica*. *Crocuses*, *Tulips*, *Hyacinths*, and *Daffodils* would be beautiful in their season. It might be filled with "*Geraniums*" and a few other bedding plants when the display of bulbs has passed away.—J. D. E.

You certainly have much ground available. I presume it is a border that requires dealing with, as it is only a foot or 18 inches wide, not a plot. You can make this little border very pretty with the help of a few good plants. The wall may be covered with creepers, such as *Jasminum nudiflorum*, *Clematis Jackman*, or *Viola*, whilst in the border put a few good bulbs, such as *Daffodils*, *Tulips*, *Hyacinths*, the pretty little *Glory of the Snow* or *Chionodoxa* *Lunellii*, *Crocuses*, and other kinds; but these will be sufficient. Then you may have herbaceous plants, the *Rock Madwort*, *Alyssum saxatile*, very pretty in the spring, when covered with golden-yellow flowers, *Achillea ptarmica* fl. pl., the *Double Sneezewort*, the flowers white and quite double, *Spring Adonis* (*A. vernalis*), *Anemones* in variety, *Antirrhinums*, *Arahis abida* (the *White Rock Cress*), *Ambristias*, *Campanulas*, especially the dwarf kinds, such as *C. fragilis*, *C. carpatia*, *C. pumila*, and the tall-growing *C. persicifolia*, for the back. Wall-flowers are very beautiful in the late spring, and also *Forget-me-nots*, both of which will succeed in this position. Select also *Coreopsis lanceolata*, which blooms throughout the summer. The *Scarlet-flowered Delphinium nudicaule*, *Pinks*, *Carnations*, and *Tufted Pansies*, *Rudbeckia speciosa*, *Chrysanthemum Mrs. DeGraange*, for the autumn; also the two dwarf *Asters*, *A. acris* and *A. smillex*, which are both remarkably showy. Fine plants for such a position also are *Lychnis viscaria*, *Gypsophila paniculata*, *Helianthus rigidus* (autumn flowering), the *Day Lilies*, *Lilium candidum*, *Primroses*, *Auriculas*, and such old-fashioned things. Of course this list might be very greatly extended, but that will make a very good beginning. Others may be added in time. I have avoided as much as possible tall strong growers, as there is not sufficient space for them in the border.—C. T.

The space is so very small there is not much scope for design or anything beyond making the soil as good and as deep as possible, and planting the flowers you love best. Early-flowering bulbs, wall-flowers, and annuals, with a few *Pinks* and *Carnations*, and "*Geranium*" or two, with two or three *Roses* on the wall, will make the border effective.—E. H.

Violet Cress (*Ionopsidium acaule*). Engraved from a photograph sent by Miss Wolley Dod, Edge Hall, Malpas.

for early greenhouse work, either sown thinly or pricked out into suitable sized pots, half-a-dozen or more tufts in each. It is a native of Portugal and belongs to the Crucifers.

4570.—A new garden.—Worms are not injurious to the soil, but if you have too many you can soon reduce them by trenching up the ground and turning it into a few runs for a few days, after which water with clear lime-water.—A. G. BUTLER.

Give the whole of the ground a good dressing of lime, which will quickly get rid of most of the worms and sweeten and improve the soil as well. The proper time and way to apply manure to fruit-trees, large and small, is in the spring, when the weather begins to get warm—say, in April or the early part of May. Spread a good coat all over the roots, let it lie all the summer, and fork what remains of it very lightly into the ground in October. A little lime is also beneficial, but this should be applied before the manure.—B. C. R.

Worms disturb the soil, but their work is often beneficial. To banish them give a good dressing of lime and soot about January. Fruit land and flower-borders may be manured any time during autumn or early winter. In the case of flower-borders, especially if they contain bulbs, the manure is best laid on the surface and forked in after the bulbs come through in the early spring.—E. H.

4572.—A new lawn.—Supposing the lawn has been newly laid with fresh turf, and that it is in good condition, there is no reason why anything should be done to it at all. Lime is a good thing for old lawns that have become covered with green Moss. It destroys the Moss and greatly improves the lawn for it is of such that Moss is troublesome. Now would be

These should be swept off and the lawn well rolled. Should there be thin places in the Grass, a little lawn-seed scattered over these early in April, afterwards raking the lawn with a sharp-toothed iron rake, and finishing off with a good rolling.—S. P.

If your lawn has been recently made with good turf it will not require dressing either with lime or manure. If the sward has been obtained by sowing Grass-seed it would do good to sprinkle some fine earth over it early in October, or what would be still better is a dressing of charred refuse, which is the remains of a smouldering fire. There is more fertilizing matter in this apparently common looking stuff than its appearance indicates. If the ground is as dry with you as it is in the West of England, where I write, two or three good soakings of water will do more good in getting the Grass established before winter than any surface dressing you can give it.—J. C. C.

4575.—Laying out a small plot.—As it is in a front garden, it is of no use to put any flowers into it which would be suitable for buttonholes. They would be certain to be picked by the tradesmen's boys or by flower-hawkers. *Roses*, *Carnations*, *Hyacinths*, *Tulips*, *Narcissus*, &c., are invariably stolen from front gardens in this neighbourhood, and probably from all others. I should recommend *Pyracantha*, *Ceanothus*, *Yellow Jasmine*, and *Ampelopsis Veitchi* for the wall, and for the front of the bed *Solomon's Seal*, *German Iris*, *Phlox*, and dwarf *Michaelmas Daisies*. These are not likely to be much meddled with.—A. G. BUTLER.

Such a border is usually occupied by the roots of plants of a more or less climbing nature growing against the wall, and in this case it is

INDOOR PLANTS.

AMONG THE BEDDING-PLANTS.

Nor another day should be lost in making up cuttings of Zonal and Fancy Pelargoniums, also of Heliotropium, Petunias, Verbena, Ageratum, Iresines, &c., that will be wanted for bedding purposes next season. All of these, and many more, may be rooted on a shelf or under a glass shade; indeed, all but the Pelargoniums will do better if kept slightly close for a time. One is too often tempted to put off this operation until frost has set down, or, at any rate, nipped the growth of bedding-plants. Because the plants are looking at their best in the late autumn we must not sacrifice our future stock by a few days' delay. Nor is this at all necessary, because it is very easy to take off a few cuttings from different places, and if done in two or three batches the growth will not be missed. A good stock of Zonal Pelargoniums is always useful, and as they can be struck in boxes and placed on a shelf out of the way until early spring, when they should be potted off, there is little excuse for a short crop next summer. I never knew the cuttings of these to look more promising; the dry and sunny season having hardened the growth into such cuttings as are sure to root freely and stand over the winter. Heliotropium, Ageratum, &c., we do not need many of to secure a good stock from next year, as these struck now will produce large quantities of cuttings when placed into heat as soon as the days turn again. Pansies and Violas will also strike very freely now, and will form healthy young stock for early spring bedding. Choose the stouter-like growths, many of which can be secured with a few roots, or at any rate with wood just ready from new roots. The strong, sappy, and flowering growth is not so suitable for propagating from. If you possess a few seeds of a good strain, they may be sown in boxes or pans at once. Sow thinly, then the seedlings can remain until you want to transplant them to their permanent quarters early in spring. They will flower well the first year, and few subjects are more showy from March until the summer bedding comes in than a good strain of Pansies and Violas. They may also be left all summer, and will still keep up a grand display of bloom, particularly if advantage be taken of showery weather to give them a sprinkling of guano or other artificial stimulant. The few flowers injured at the time will not matter much, as they would be spoilt by the weather, while the great advantage of the sport afforded by the guano will be noticeable all the summer. P. U.

4574.—**Tuberosee.**—The best things to do with Tuberosee when they have done flowering is to put them into the dustbin; they are of no further use. This is the one serious drawback to growing these bulbs.—A. G. BUTLER.

— After having once flowered the roots are useless, and must be thrown away. No treatment that can be afforded will cause them to bloom a second time in our climate.—B. C. R.

— It is not much use endeavoring to use these for a second crop of blooms. They require special treatment, and very seldom please. Tuberosee are grown with the express purpose of yielding one good crop of bloom after they reach the purchaser, and it is not worth the trouble of trying them the second season.—P. U.

— These bulbs are of no use a second year. Our climate will not ripen them sufficiently to flower well; but you might plant out in the border, sheltering them with a mound of ashes, and see what comes of it.—E. H.

— The bulbs of the Tuberosee are not usually kept after they have flowered, as they have a tendency to degenerate with our system of culture under glass; but they may be dried off, and either kept in the pots with the soil perfectly dry, or they may be taken out and laid in quite dry sand. The bulbs are imported at intervals of three or four weeks for successive bloom; as soon as they are potted in moderately moist soil place the pots in a bottom-heat of about 88 degs. or so, in a warm greenhouse or cool plant stove temperature. Do not water at the roots until growth is made, and when this plants are in growth syringe freely to keep down red-spider. They should also be kept in a light position near the glass.—J. D. E.

4578.—**Peat for Azaleas.**—I made up a peat bed for Azaleas ten years ago only 1 foot deep, and they have flourished well ever since. They require much the same treatment

Rhododendrons, and it is not worth while to plant either the one or the other in soil such as would only enable the plants to live and not flourish. A third of the loam may be mixed with the peat, and the soil ought to be drained; stagnant water causes the plants to become covered with Lichens. Although the plants have done well in a depth of 1 foot of prepared soil, I would have made the bed 18 inches deep if I could have obtained peat easily, but I had to get it at a distance of 80 or 90 miles.—J. D. E.

— A made soil of 2 feet deep would be sufficient for these. You need not use peat and vegetable refuse for the whole of it. If you were to put a third of each with the same quantity of your natural soil they would probably do better, especially if you could add a little coarse sand.—P. U.

4503.—**Compost for Oleanders.**—These handsome plants will succeed almost equally well in either a loamy or a peaty medium, but as they flower more freely in the former it should be preferred. They even succeed in a pure turfy or fibrous loam of good quality only, mixed with enough sand to keep it open; but perhaps the best compost consists of four parts of such loam to one part each of peat and leaf-mould, and one eighth of the whole of sharp sand. Drain the pots well and make the soil quite firm, especially in the case of large specimens.—B. C. R.

— Loam and peat or leaf-mould with enough sand to keep it open will grow the Oleander well—may two-thirds of loam to one-third of leaf-mould or peat, well broken up with the spade, but not to be sifted except for potting off cuttings.—E. H.

ROSES.

Rose Grace Darling.—This is a splendid hybrid Tea-scented Rose for a small garden. The reason is that the plants, when upon the Brier-stock, are remarkably vigorous, and bloom over a very long season, from quite early summer until the frosts come. The flowers are produced with great freedom, and they are distinct and pleasing in colour, cream, touched with rose-pink. They are produced on strong stems, and above the fine green leafage, so to speak, something in the way of Ernest Metz. Grace Darling is certainly one of the best garden Roses.—V. C.

4548.—**Roses from cuttings and seeds.**—Beyond the question of novelty, raising Rose-trees from seed has not much to recommend it. However, it is not a difficult matter. When the hips which contain the seed are ripe, gather them, taking out the seed, saving it in a dry place until the following March, when it should be sown in sandy soil in a gentle bottom-heat, which ensures a much quicker germination than though the seed was sown in the open. Gradually harden off the plants and finally plant them out in the open. Roses of many kinds are easily raised from cuttings made from the current season's growth, cutting the shoots into 8-inch lengths, rejecting the upper part of the shoot, owing to its being unripe and, consequently, not in a state to send out roots. A border at the foot of a west wall is a good site for the cuttings. Chop out a trench 4 inches deep with a spade, sprinkling at the bottom some sand or road grit. In this roots form quicker than in soil. The cuttings are placed in the trench 3 inches apart, having been first cut square below a joint, removing the bottom leaves. Tread the soil firmly about the cuttings. This is most important. If the cutting is constantly moving it cannot make roots. Dig more ground and take out another trench 10 inches from the first. The end of September is a good time to put in the cuttings. Early in November lay a 2-inch thickness of decayed leaves, Cocoa-nut-fibre refuse, or even coal-ashes on the surface between the rows, the object being to prevent the frost from lifting the cuttings by the upheaving of the ground, and thus loosening them at the base. In a year's time nice plants should be available.—S. P.

Rudbeckia speciosa.—What a splendid plant this is for a small garden, or for any garden, however large! It persists in blooming from summer until quite the late autumn, and this year has been one of the gayest of hardy plants. The flowers are intense yellow, set off by a black centre, and borne so freely as to make a dense mass of rich colour. It grows strongly,

and even when only a small clump is planted the effect is remarkably rich. There are few better all-round perennials than this, and this season, in spite of drought and accompanying drawbacks, has bloomed remarkably well.—V. C.

RULES FOR CORRESPONDENTS.

Questions.—Queries and answers are inserted in *GARDENING* free of charge if correspondents follow the rules here laid down for their guidance. All communications for insertion should be clearly and concisely written on one side of the paper only, and addressed to the Editor of *GARDENING*, 37 Southampton-street, Covent-garden, London. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Unanswered queries should be repeated. Correspondents should bear in mind that, as *GARDENING* has to be sent to press some time in advance of date, they cannot always be replied to in the issue immediately following the receipt of their communication.

Answers (which, with the exception of such as cannot well be classified, will be found in their different departments) should always bear the number and title placed against the query replied to, and our readers will greatly oblige us by advising, as far as their knowledge and observations permit, the correspondents who seek assistance. Conditions, soils, and means vary so infinitely that several answers to the same question may often be very useful, and those who reply do well to mention the localities in which their experience is gained. Correspondents who refer to articles inserted in *GARDENING* should mention the number in which they appeared.

4504.—**Aspidistras.**—What is the best treatment for Aspidistras? What soil is needed?—M. R.

4505.—**Making leaf-manne.**—Which is the best way of making leaf-manne?—J. G. LOUDON.

4506.—**Planting a Pentstemon.**—When would be the best time to plant a Pentstemon?—FLUENGA.

4507.—**Daffodils for a small border.**—What Daffodils are best for a small border?—M. Y. L.

4508.—**Greenhouse during frost.**—What is the best material to cover the glass of a greenhouse with to help keep out frost?—JUCHAN.

4509.—**Seaweed and Asparagus.**—Will anyone kindly tell me where I can obtain a truckload of Seaweed on the Great Western Railway?—ASPARAGUS BED.

4500.—**Scale on a Rose.**—I have a Gloire de Dijon Rose which is infested with brown scale. What should I do with it? It is a large one, and potted out.—G. P. O.

4501.—**Paring and burning turf, &c.**—Would some reader who has had experience in the above method of treating loam kindly give time and method of operation?—SPADE.

4502.—**Aspidistras.**—I should be glad to know how to prevent Aspidistras leaves (the variegated ones) turning green? What treatment to make them variegated?—ESQUINAS.

4503.—**Fear for a wall.**—Will someone kindly inform me as to the best desert Pea to plant to grow up a wall facing south-east, in a good sandy soil? Also treatment of same?—M. R.

4504.—**Marguerites for winter.**—Please say how to treat Marguerites for winter flowering in a room? I have the two white and the yellow. They have not flowered much as yet.—M. Y. L.

4505.—**Early Vines.**—Will someone kindly inform me when is the best time to prune early Vines, and also what is best to paint the rods with, and what quantity of each to mix?—ANATHEU.

4506.—**Wooden labels.**—Will someone kindly tell me how to prepare wooden labels for writing on with common lead-pencils, such as are used by nurserymen and florists?—JAMES HOS.

4507.—**Apple-trees in bloom.**—A large number of my dwarf Apple-trees are now in bloom. Will this affect next year's crop, and what is best to be done now—that is, if anything can be done?—G. R.

4508.—**Chrysanthemums from seed.**—Would any reader of *GARDENING* kindly give me information how to hybridise and save Chrysanthemum seed, and also how to grow them from the same?—INTERESTED ONE.

4509.—**Treatment of an Orange tree.**—Would someone kindly tell me how to treat an Orange-tree to make it bloom the beginning of June? It flowered about April last year. It has been in a conservatory ever since.—WELDON.

4510.—**Plants for a conservatory.**—Will "J. C. C." be kind enough to state names of plants, and when to sow seed and strike cuttings of each plant to keep up a perfection of bloom all the year round in a heated conservatory?—E. M.

4511.—**White Roses.**—Would someone kindly give the names of four dwarf pure-white Roses, including a fine Chrysantheum to place at the four corners of a garden in a well-shaded gravel-plot? Any answer or suggestion will be gratefully received.—BASSIN.

4512.—**Clover seed and Strawberry.**—Will someone kindly tell me the proper time to sow Clover seed among Strawberries, so I saw one of the papers it was advisable to have it, to keep the weeds down and the fruit clean? Is this so—E. H. H.

4513.—**White Tomato-ry.**—Will someone kindly inform me if the small white ry often seen on Tomatoes is injurious to Chrysanthemums? Would it be advisable to stove a large greenhouse in which these pests are before housing the Chrysanthemums?—T. C.

4514.—**Akebia quinata.**—Is it unusual for Akebia quinata to bear fruit in this country? One here on the wall of a house has fruits as large as a Lemon, which split open and have rows of black seeds. It has been here ten years, and bears fruit every year.—SPUTA.

4615.—Tea Rose for a west wall.—Would "T." kindly give the name of the Tea Rose for a west wall? I want those delicate shades of colour not to be had in H.P. Roses. As my space is limited I want the best possible.—FIFESHIRE, Scotland.

4616.—Packing Lilliums.—Will it be safe for me to pack my Lilliums to Coons-nut-fire as they die down? I am thinking of leaving my house, and should not get another until the spring, and as I have a great number in the garden and pots, should like to store them.—MRS. FLOWER.

4617.—Treatment of Camellias.—Will someone kindly give me some information concerning the treatment of Camellias? The small leaves of my plant change colour, while the larger ones remain green. The plants have been kept in the open air during summer months.—J. W. E.

4618.—Field mice.—Will someone kindly tell me how to rid my garden of field mice, which have lately appeared in many places, and are eating various plants? My garden was newly made this spring, and is the only one out of a large field. I have got rid of moles with traps, but now mice have appeared.—MOSLEY.

4619.—Chrysanthemum for show.—I should like to grow about thirty Chrysanthemum next year for large exhibition blooms, and I will be obliged if you or any of your readers will name the best twenty-four for this purpose, and give any hints regarding their cultivation for this purpose.—C. W. GENTLEMAN.

4620.—A legal agreement.—I have a house on a three years' agreement, and wanted to allow the tenant for say shrubs, &c., he might plant during the term. That is now fifteen years ago. No other agreement has been taken, but he has stayed on as a yearly tenant. Am I now bound to carry out my promise?—H. G. W.

4621.—Asparagus-bed.—I see your correspondent, "E. Hobday," recommends stripping off the seeds on Asparagus-tops at once. Be good enough to tell me what should be done with these seeds? My Asparagus bed is thin in places. Could these seeds be used by placing in the bed to secure more even heads throughout the bed?—J. N.

4622.—Mealy-bug.—Will someone kindly tell me how to get rid of what I call mealy-bug? I have only had a greenhouse two years, and am quite a novice in growing fruit under glass. I have two Grape-Vines and about twenty Tomato-plants in a house 16 feet by 11 feet. I have tried burning Tobacco-paper. The best first came on the Tomatoes.—W. W. RICHARDS.

4623.—Vines in a cold house.—I should be glad of some advice. The vines have had artificial heat in past years, but I want to grow them naturally. The Grapes have been good. What is the new treatment with regard to ventilation, watering, &c.? There is an inside and outside border. When and what sort of Vines should be put in in place of dead ones?—ANATRA.

4624.—Spiraea japonica.—Following directions in GARDENING, I planted Spiraea japonica in the open ground after flowering in the spring. The foliage has sprung up again, and just lately plants have thrown up flower-buds, which are, however, dying off. Can I force them again this winter, or must they rest a year? And, if so, when must they be potted up next autumn?—JURONGAU.

4625.—Shrubs in flower-beds, &c.—Will anyone kindly suggest a good way of planting two large flowers with shrubs and perennial plants (paranatal only), so that they may look bright and orderly with as little outlay as possible either of time or money? The soil is sandy, and the garden plots are in terraces one below the other, facing to the south-west and divided by a path.—ANATRA.

4626.—Bine Gum and variegated Agaves.—Can I leave Blue Gum and variegated Agaves out all winter close to the south-west coast? They are fairly sheltered, but last winter, though we had no snow we had weeks of hard frost. If anyone can kindly advise me I shall be obliged, as both these are admirably in the summer, and I remember an Agave in a Devonshire garden, arranged in GARDENING last year.—R. L.

4627.—Yellow-spined Arums.—A few months since a writer in GARDENING was speaking of two kinds of Yellow-spined Arum Lilies, and recommended one of the two, which, if I remember rightly, was Pandovali. If that writer should happen to see this would he kindly say where a plant could be obtained, and the probable price for a flowering root? I mean strong enough to flower the coming winter or spring.—YELLOW ASH.

4628.—A town garden.—My garden, which is in Clapham, has a border of 3 feet 6 inches wide, in which I have just planted border Carnations. Will one of your readers kindly say whether these will require any protection during the winter, such as a mulch of Coons-nut-fire, stable-manure, or ashes? Would the fibre or manure cause the plants to damp off? Any information as to the way in which I can best keep them will be greatly esteemed.—G. SANDERS.

4629.—Building a glass-house.—I have a sashes, with which I am about to construct a glass-house, intended for growing Rhubarb in winter, Tomatoes in summer, and Chrysanthemum in autumn, in beds on each side of the house, heated by a fire. Span roof 6 feet high to the ridge inside, 30 feet long by 10 feet wide, running south-south-east, with a ventilator at the south end; door north, and four ventilators on each side, immediately under the eaves. Is it necessary to have ventilation at the top as well?—J. SEATON.

4630.—Bougainvillea glabra.—I have a young plant of this I bought last June in a 4-inch pot; it is now 4 feet high, with side shoots about 8 inches long, looking very healthy in a warm house, but is quite pot-bound. Shall I report it now or wait till after flowering next spring? Should the plant (as it is so young) be allowed to rest a few days during the winter, and will it require pruning before flowering, as the wood so young? I shall feel obliged if someone will kindly give me some information on the subject.—L. E.

4631.—Treatment of fruit-trees.—I have a moderate-sized garden, in which I have some thirty or forty trees, consisting of Apple, Pear, Cherry, and Plum, figs, bush and some standards, but I find them getting too large, as they overshadow almost everything else. How

far may I prune them back without lessening my crop of fruit? What I really want is a scissor which I may cut off all the wood made this year without injuring the tree, if the same rule applies to all, and the best time to operate?—ROBERT W. GREEN.

4632.—Winter Pears.—I should be much obliged for some advice about the gathering and keeping of winter Pears. We have a large tree of Winter Niella which now is covered with fine Pears. What is the best way of storing and keeping them till they are fit to eat? We were advised one year to hang them up by the stalks, but with such a quantity it would be almost impossible, and I did not think it answered as well. Should they be kept in a warm place? And would it hurt them to be kept to the dark? Any hints thankfully received.—K.

4633.—Rose "W. A. Richardson."—I have a Wm. A. Richardson Rose in my greenhouse, S.W. aspect, heated to keep out frost. The Rose was purchased last winter in a 4-inch pot. It had two shoots 2 feet long, and this spring bore two flowers. It is now in an 8-inch pot, and has this year made about 8 feet, 6 feet, 4 feet, 3 feet, 2 feet long respectively, which are still growing. It is trained along the back of house. What treatment will it require from now to time of flowering? How should I proceed after it has flowered? When will it require repotting? It is entirely free from insects, and looks very healthy.—FRITH.

4634.—Management of a garden.—I have a small garden, facing south. We got the early sun, and everything seems to grow, but my fascination is Roses. Last year I at haphazard ordered a bundle of forty, and gave them a chance; half died, and the other half are alive and well, although have not flowered very much. Would anyone kindly say about twenty should be planted this year for steady growth? The principal ones I have now are La France, Beauty of Waltham, Barouers Rothschild, Prince Camille de Rohan, Comtesse Oxford, Mezes Chart, Camille Bernardin, and Gloire de Dijon.—ROBARIAN.

4635.—Rose "Gloire Lyonnaise."—Thanks for advice as to growth of this Rose. In answer to "J. O. C." as to the flowering of the above Rose when pegged down, I have found that in spring it gave a few flowers at the tips of some of the shorter upstanding branches, but on the branches that were pegged down, the shoots grew level with the ground to about 1 inch from the bloom, and then turned suddenly upwards, which, of course, made an awkward shape for cutting. I had already thought the Rose more suitable for training, and since the suggestion given by "J. O. C." have almost decided to train it over an archway at the top of Grass steps. I shall be glad of answers to a query I am inserting.—MICAWORK.

4636.—Treatment of Begonias.—I have just commenced to grow Begonias. I have some very fair-sized plants, from three to eight flowering branches or stems on each plant. They were grown in black loam, tort, sharp sand, manure from Leek-ranch of last year, and leaf-mould, in about equal proportions. I kept them in a greenhouse, gave them plenty of air, and watered freely every day. They were exposed to the sun. My plants did very well, flowered freely, but the flowers dropped off after two or three days. Is the casting off of the flowers a habit of the Begonia? If so, what would you recommend that would have the effect of counteracting it? Or, if my treatment of them causes the flowers to drop off, how should I treat them now for the winter?—YOTTI.

4637.—Heating a small greenhouse.—I have a small greenhouse, 12 feet long by 3 feet wide, and rather high (not so covered) with a levelable, being part of an existing building. It is heated by a No. 1 Loughborough boiler, with two 4-inch pipes, each 5 yards long, along ead and side of building, due no top of boiler with smoke pipe 10 feet high straight up through the roof. It does not answer satisfactorily and wastes considerably. At times the draught is so great the fire will not keep in all night with both doors closed and damper nearly closed, when it smokes and smokes very much, and is caused by blocking up of smoke pipe with soot. I burn nothing but coke, and have the pipe swept every six weeks when fire is on day and night. I follow instructions for banking up at bed-time most carefully. Directions also recommend kelping supply cistern filled over opening into top pipe, but if I do so water rises and overflows, flooding the floor and filling house with steam. I am told there ought to be a trap to prevent the supply cistern from overflowing into open air. Is this so? Any advice will be gratefully received.—PETERUX OX.

4638.—Fruit farming.—Two of us intend to try and get a living at fruit farming. We have purchased 12 acres of freehold land, free of title and land tax; this has high, is well drained, and slopes gently. South aspect, medium loam. All kinds of fruit do well in the neighbourhood. Seven acres are old pasture at present, 5 acres arable; we have put it in nice condition for setting. We have no particular market, but should have to find one. We are one mile from station, and thirty-five from London. We are anxious to grow other crops, but have had very little to do with fruit. Will a practical grower give us advice on the matter? Is it advisable to plant the whole of the land soon as possible, or say 2 or 3 acres at first, and see how we get on? We thought of planting standard Apples about 30 feet apart, bush and pyramid Apples 10 feet apart, with Currants (meat black), and Gooseberries 5 feet apart. Do you think it better to start with one crop, or market? Any suggestions will be highly appreciated. I might add that we shall not want any profits for two or three years. The land is divided into three fields, protected by hedges.—G. LAWRENCE, Halegh, Essex.

4639.—Florists' Tulips.—In GARDENING of 19th June, 1892, there appeared an article on Florists' Tulips by "Mr. J. Douglas." Having formed a small collection of the best-known named varieties, I shall feel obliged if he, or some other of your readers interested in the cultivation of these beautiful flowers, will inform me whether the bulbs may be grown under glass in pots, and, if so, what size of pot and depth of soil is necessary? On a former occasion I received your very kind and helpful reply, and am indebted to "Mr. J. O. C." for the hints given. I tender him my best thanks, and will be glad to see his counsel very useful. So I am now emboldened to ask for instruction in growing Florists' Tulips? Being near town I do not think it probable I

should succeed well in the open garden; besides, the bulbs, though not comparatively cheap compared with prize Tulips, are not so early, and are not, I think, so scarce, and not cheap enough to cultivate as ordinary Dutch Tulips in the open garden. I shall feel obliged by all the advice you can give me. The glass-houses in which I propose to grow the Tulips in peats, and which I stage in level (divisions pea shaped), and lead lined. Would it be better to bed the bulbs thereon in soil and discard the peat? In what depth of soil? I can regulate water supply and drainage. If good blooms can be obtained in peat I prefer to use them.—J. FOAT.

4640.—Grape-Vine in a greenhouse.—I have a Grape-Vine five years old growing in a greenhouse, the fruit of which cracks to a great extent just as the berries are turning colour. The house (span-roofed) is about 12 feet wide, 30 feet long, 10 feet high inside at highest point, roof angle about 45 degs., has top and front ventilators, roots of Vine to outside prepared border, 8 feet deep, 6 feet breadth, and same in length; well top-dressed each winter. I had last year two rods staked across the house about 6 feet 6 inches from glass, bearing thirty-six bunches of splendid Grapes for size (a variety of Black Hamburgh, I believe), but they did not colour, and cracked very much. A miscellaneous collection of plants is grown in the house on side and centre stages; the pathway is kept wet till the days shorten, when less water is used; leaves syringed last year till fruit began to colour. This year I have two side canes in addition to the two arched ones, each about 8 feet long, the four rods or canes bearing seventy-five bunches. I have not syringed the leaves at all this season, have soaked roots of Vine several times, but not since colouring has commenced. The berries are cracking again, though to a less extent than last year, the Grapes are ripening but colouring badly. Top air on night and day now, foliage fairly healthy, no fire-bait since the spring. Would it be any advantage to fasten the rods close to the glass during the winter when the house is kept at about 45 degs. I am obliged to grow other plants, and do not wish to sacrifice Vine, but would appreciate any advice which will improve it. I may say I ripen fruit and colour well on two pot-Vines of same variety (cuttings from it) to same house.—W. H.

Names of plants and fruits.

"I am sorry to hear of the loss of your plants, which should be addressed to the Editor of GARDENING ILLUSTRATED, 37, Southampton-street, Strand, London, W.C.

Names of plants.—"Lycocaulis."—No, not an Aristolochia but Stigmaphyllon alatum.—R. W. DUNCEAN, Campanula garganica; 2, Spiraea umbellata probably, but not specimen. Others too much of character to recognize.—SPOTTIS. Send again when in flower.—ROSS. Please send in flower and give name and address.—G. E. OCHS. A Dies apparently, but specimen was so much past its best that we cannot name accurately.—J. C.—Adiantum obovatum lacum.—JANINUS.—Clematis vitalba.

Names of fruits.—W. DAVIES.—Apples: 1, Cerrilla Codlin; 2, Local kind, not recognized; 3, Blenheim Orange; 4, C. S.—Siberian Crab.—S. K. C.—Apples: 1, Blenheim Orange; 2, Lord Suffield; 3 and 4, Yorkshire Beauty; 5, Not recognized; 6, Reining Redding.—J. W. PARSONS.—Williams' Pear, Chrétien, & Hildard.—Graps Buckland Sweetwater.—Hayward.—Apples: 1, Cox's Orange Pippin; 2, Northern Greening; 3, Tower of Glamis, 4, Mère de Ménage; 5, Cardale Codlin; 6, Beak no further; 7, King of the Pippin. Pears: 8, Williams' Bon Chrétien; 9, Baurré de Caplaumont; 10, Marie Louise.—R. WILKINS LION.—We cannot name the Pear from such poor specimens. Probably local sorts.—C. JONES, Fairy-Apple.—A very fine specimen of Apple, Blenheim Orange.—D. A. AINSIE. 1, Mère de Ménage; 2, Hawthorned. Pears: A, Marie Louise; B, Napoleon.—MIDLAND.—Apples: 1, Mère de Ménage; 2, Cardale Codlin; 3, Yorkshire Beauty.—F. GAMBLE.—Apples: 1, King of the Pippin; 2, Local sort. Count name.—A. A. S.—No doubt the Apples are wrongly named, and we should say they are probably local sorts that have got mixed up with others.—E. J. H.—Apples: 1, Kerry Pippin; 2, Cellini; 3, Beak no further. Pears: 1, Autumn Bergamotte; 2, Autumn Crassane; 3, Vicar of Winkfield.

TO CORRESPONDENTS.

We should be glad if readers would remember that we do not answer queries by post, and that we cannot undertake to forward letters to correspondents, or insert queries that do not contain the name and address of sender.

W. F. RICHARDS.—By all means put in a new boiler before winter sets in. Any plan of packing would be useless.—AN ENQUIRER.—Send a specimen of the Sedum which you refer to, to E. J. H.—H. SMITH, Blackwater.—No; send them to K.W.—W. BOND.—Eaten by some insect apparently, but we cannot say what. If you should see any insects at work please send some here in a box.—MICEBER.—Please send a branch of the Rose.—J. J. O.—Apply in Messrs. G. BUNYARD, fruit-growers, Maidstone, Kent.

"Gardening Illustrated" Monthly Parts.

Price 6d.; post free, 8d.

"The Garden" Monthly Parts.—This journal is published in weekly bound Monthly Parts. In this form the colour plates are best preserved, owing to most sales for reference previous to the issue of the half-yearly volumes. Price, 1s. 6d.; post free, 1s. 9d. Complete sets of volumes of THE GARDEN from its commencement to end of 1892, forty-two vols., price, cloth, 450 13s.

London: 37, Southampton-street, Strand, W.C.

URBANA-CHAMPAIGN

NEW PHOTOGRAPHIC COMPETITION FOR 1893

Owing to the early date at which our prizes were announced to be sent in this year there was not time to properly take many kinds of outdoor fruits, flowers, and vegetables; therefore we offer further prizes for these things, to be competed for during the present year; allowing till the end of November for the work.

Class I.—FLOWERING PLANTS.—A prize of FIVE GUINEAS to the sender of the best collection of photographs of flowering plants grown in the open air or under glass. This series may include flowering trees and shrubs of all sorts.

Class II.—BEST GARDEN FRUITS.—A prize of FIVE GUINEAS for the best collection of photographs of any of our good garden fruits: Grapes, Peaches, Apples, Pears, Plums, or any other fruit grown in Britain. Fruits should not be crowded in dishes if good and clear photographs are sought.

Class III.—BEST VEGETABLES.—A prize of FIVE GUINEAS for the best collection of photographs of best garden vegetables. The object of this is to get fair representations of the finest garden vegetables under the old genuine names. We do not want to exclude real novelties when they are such. In all cases the name of the variety should be written on the back of the photograph.

Class IV.—AUTUMN FLOWERS AND LEAVES.—A prize of FIVE GUINEAS will be given for the best series of photographs of autumn flowers and leaves in the house in a cut state for vase, table, or other kind of indoor decoration.

WHAT TO AVOID.—Cut flowers or plants should not be arranged in vases with patterns on them. Backgrounds should be plain, so as not to come into competition with the beautiful flowers. Figures of men or women, barrows, watering-pots, rakes, hoes, rollers, and other implements, iron railings, wires, or iron supports of any kind, labels, and all like objects should be omitted. Dwarf flowers are ineffective when taken directly from above. The camera should be brought low down for such. All photographs should be mounted singly, and not several on a card. The photographs should not be less in size than 5 inches by 4 inches. The following are the rules to be observed by all competitors:—

In any of the departments, if no collection of sufficient merit be sent in, no prize will be awarded. All competitors not winning a prize will for each photograph chosen receive the sum of half-a-guinea.

FIRST.—The photographs may be of objects in the possession of either the sender or others; but the source whence they are obtained must be stated, and none sent the copyright of which is open to question. There is no limit as to number, and no fee to pay. The Editor is to have the right of engraving and publishing any of the chosen photographs. The photographs may be printed on any good paper that shows the subjects clearly; but those on albumenized paper are preferred for engraving.

SECOND.—The name and address of the sender, together with the name and description of the object shown, should be plainly written in ink on the back of each photograph. This is very important.

THIRD.—All communications relating to the competition must be addressed to the Editor of GARDENING ILLUSTRATED, 37, Southampton-street, Strand, London, W.C., and the class for which the photographs are intended should be marked on the parcel, which must also be labelled "Photographic Competition." All competitors wishing their photographs returned, if not successful, must enclose postage stamps of sufficient value for that purpose.

EVERYONE WHO HAS A GARDEN GREENHOUSE, OR WINDOW BORDER SHOULD READ A PAMPHLET, POST FREE.

HOW TO INCREASE THE FRUITS OF EARTH.

By G. H. WILK, F.R.S., F.C.S. Trinity Col., Dublin. Contains full particulars of very remarkable discoveries relating to Plant Life. Shows how crops of vegetables may be largely increased, lovely flowers grown to perfection, and fruit-trees made to bear in abundance. Selections from Hundreds of Testimonials. Post free from JAKEMAN & CARVER, Printers, Hereford.

THE CHALLENGE HOT-AIR & WATER HEATING APPARATUS.

Adapted for Oil, Coal, and Gas. Twice as effective as the best ever offered to the public.

Consists of 18 ft. 2 1/2, 21 ft. 2 1/2, and 4 ft. 3 1/2 pipes. Equal to 50 ft. of 2 in. hot-water pipe. Will burn 1 gallon in 48 hours only, or 4 feet of gas per hour. Prices from 21s. Send for particulars. Hundreds of testimonials. The only Hot-water Engineers, 139, CHEAPSIDE, E.C.

THE TRADE SUPPLIED.

ROSES.

NOTES ON ROSES.

THE PAST SEASON.—The summer that has now passed has not been altogether favourable for these, as the drought has been very severe, the flowers quickly fading both on the plants and when gathered for the house. I expect to find Roses very expensive this year, although in these nurseries I have seen they look remarkably strong and healthy. It is curious to notice, in briefly reviewing the past season, that the dark Roses in particular have succeeded remarkably well, which is exactly opposite to what one would expect. The usual case in very hot seasons is for the dark flowers to get completely burnt up with the sun, the petals thus losing their rich velvety and characteristic beauty. That fine kind, Prince Arthur, has been very good this year, and one reason why the dark Roses are such favourites is because, I think, their colour is rich and the fragrance very strong, and fragrance is not too pronounced in many of the newer Roses in particular. Xavier Olibo, Prince Oamille de Rohan, Pierre Notting, Lonie van Houtto, Fisher Holmes, Reynolds Hole, and Sultan of Zaehihar, are the best dark Roses, practically, and form a very good selection. The worst of such kinds, however, as Pierre Notting is that they are not constant; but it is seldom that such a season as this occurs. Still, it is a fine Rose, very fragrant, and deep in colour, well worthy of a place in gardens.

TEA-SCENTED ROSES are blooming exceptionally well this autumn, and have done so throughout the summer, but the autumn bloom, to my mind, is as charming as that of July. Ernest Metz has proved a splendid variety this year, and has been shown well on many occasions at the exhibitions. It was raised by the French raiser, Guillot, in 1853, and the flowers are very distinct and delicate in colour—carnation-rose is the best description, perhaps the centre of the flower of a brighter tint—while each bloom is borne on a sturdy erect stalk. Writing of Tea-scented Roses reminds me I saw a wreath the other day composed of nothing but Marie van Houtto flowers, and a more exquisite effect I have never seen. This fine Rose, raised by Duocher in 1871, is very beautiful this year. There is great charm in the flowers, which are soft yellow, with the petals edged with rose. Of the newer kinds of Tea Roses, the following have been very satisfactory: Cleopatre, especially early in the season, was delightful, the flowers of a flesh tint, shot with rose, and the petals broad. Corinthia, one of Mr. William Paul's, Welltham-cross, raising, the flowers flesh in colour, marked with rose, and coppery tint. The Bride, Dr. Grill, Ethel Brownlew, Mme. Hoste, Marquise de Vivens, Princess Beatrice, and Sonvenir de S. A. Prince. These are either quite new or comparatively so, and have been very free this year.

GARDEN ROSES.—It is a pleasure to see that the garden Roses—those not suitable for exhibition—are growing greater in public favour each

year. I hope that they will be still more grown, as without the Chinas, Polyanthas, Moss, and other sections the garden loses greatly in interest. I was noticing the other day a bed of the Polyantha varieties, which were a mass of bloom, although late in September. The same remarks apply to the Chinas, which are amongst the most delightful of Roses, very free, and in every way worth a place in both large and small gardens. The most recent addition to the Chinas is Laurotte Mercancy, which has comparatively large flowers, rose, suffused with yellow, and they are produced very freely. The Green Rose, it may be interesting to mention, belongs to the China class. The flowers are quite green, and it is not easy to distinguish the petals from the leaves. The Crimson China is one of the best, the flowers such a deep-crimson colour, and the plant is remarkably hardy. Of course, the common China Rose is the Monthly Rose, and a very bright little flower. This was raised in 1796 by a raiser named Parsons.

CLIMBING ROSES.—I recently saw the beautiful Gloire de Dijon Rose written against, and other varieties recommended as possessing greater value. But I defy anyone to select a more useful, all-round Rose than this Rose of Jacotot's, who sent it out in 1853. I have had a fine lot of blooms from a plant only put in last January, and it has made splendid growth, long shoots full of vigour. Then the flowers are rich in colour, and of splendid fragrance. A sweeter English pictorial one scarcely to be got than produced by a Gloire de Dijon tumbling over a cottage, mounting up even to the chimney, and sending its fragrant flower-laden shoots into the latticed window. Speaking of climbers, I rather like the new L'Idéal; its red and yellow flowers are very pretty in the bud, and show when fully expanded. It is a bright and pleasing Rose, and very strong-growing.

HYBRID TEA ROSES.—This is an important class, but much confused. It would be well, I should think, to put some of the varieties with the Hybrid Perpetuals, and the others with the true Teas. Caroline Testout is a good addition. The flowers are large, of a salmon-pink shade of colour, and very distinct. But the gem of this group is Angustine Guinoisseau, which succeeds very well as a dwarf on the cutting Brier or as a standard. Its flowers are white, with a delicate rose centre, and delightfully sweet.

V. C.

4615.—Tea Roses for a west wall.—I have pleasure in naming twelve good Tea Roses, and "Fifeshire" will do well to send the whole list to a nurseryman when ordering, in case he may be out of one or two of the varieties. I have named six strong growers first, and six of medium growth later. It is always my plan to plant the extra vigorous varieties alternately with those of ordinary growth. I thus secure a good show all the season, and, at the same time, am certain of covering the whole of my wall. Strong growers are very apt to be rather bare at the bottom, and this space is filled in by the shorter varieties. If "Fifeshire" is contemplated, planting ten plants of climbers, a dozen if planted in the manner suggested, will be none

too close. Extra vigorous growers: Belle Lyonnaise (canary-yellow), Climbing Perle des Jardins (deep-yellow), William Ailen Richardson (orange and apricot), L'Idéal (copper, red, orange, and peach), Mme. Chauvry (copper and nankeen-yellow), and Teur Bertrand (clear fawn-yellow). Ordinary growers: Anna Olivier (orange and buff), Dr. Grill (rose and copper), Ernest Metz (salmon-flesh), Françoise Krüger (copper, yellow, and peach), Innocente Pirela (creamy-white), and Jean Duocher (salmon-yellow, with distinct coppery end and blood shadings). All of these are distinct and sweet scented.—P. U.

4600.—Scale on a Rose.—This is about the very worst pest the plant could be troubled with, few remedies being thoroughly successful without harming the Rose. Cut off all the wood you can spare, also the foliage which is ripe, and burn it at once. Then procure a cake of Gishurst Soap and a small painter's sash brush or "tool," as it is sometimes called. Drop a little paraffin upon the soap, dip the brush into warm water, and then make a lather. Work the brush all over the wood affected with scale. The paraffin will run into all crevices, and if you do not use it too strong, and afford a thorough syringing directly after, no harm will be done. Old scale wants a lot of killing. Keep the wood syringed with some good insecticide every third day for the next fortnight.—P. U.

—Dissolve 6 oz. of Gishurst Compound in a gallon of hot water, or less quantity can be made in proportion. The scales will be found principally on the old wood, and if the liquid compound is brushed well over the branches with a small paint-brush the insects will die. There are other modes of treatment, but I have always found this effectual and very economical.—E. H.

4633.—Rose W. A. Richardson.—Your Rose appears to be doing very well, so that you cannot do better than to continue the same treatment. The long shoots may be cut back one-fourth their length in the winter, as I find it flowers better when slightly pruned. As soon as the first flowers are over in the spring it will require more root-room, if you have space for the branches to extend; a pot 12 inches in diameter will not be too large. If you cannot give it a larger pot you must supply the roots regularly with manure-water.—J. O. C.

—You are fortunate in possessing such a healthy and well-grown specimen of this Noisette Rose. I would suggest that you keep it a little dryer than usual, and admit a fair amount of air; or else extend it outside in some sheltered nook for a week or two. This will induce better ripening of the long shoots. Do not prune it except to cut away the tips that are not efficiently matured by the early part of next January. I cannot recommend your reporting it before blooming is over, but you can assist it with liquid-manure after the new growth has developed somewhat.—P. U.

4635.—Rose Gloire Lyonnaise.—I wish to thank "Miaowbor" for the information he sends regarding the behavior of this Rose, as it strengthens my opinion that I had already formed that it is more suitable for training on a pillar than for pegging down. A very good standard was given of this Rose in the Garden last week, but it does not show the capacity it

possesses of producing large and handsome flowers when cultivated on a pillar. I am acquainted with a plant so treated that occupies the corner pillar of a verandah where the east wind reaches it in full force; yet it is unharmed, and produces every year such large and perfect flowers that the figure I have referred to gives but a poor idea of its character. When grown under suitable conditions I have no hesitation in recommending this correspondent to train it in the way he suggests.—J. C. C.

4634.—**Management of a garden.**—"Rosarian" will find the following twenty-four Roses hardy, and quite distinct from those named in his query. If planted early they should thrive a great deal more satisfactorily than the forty he mentions, especially as the situation is so good. H. Perpetuals: General Jacqueminot, Fisher Holmes, Mrs. John Laing, Ulrich Brunner, Abel Carrière, Dr. Andry, Suzanne Marie Rodocanachi, Mrs. G. Dickson, Heinrich Schultzeis, and Elie Morel. Tea-scented and Noisettes: Anna Ollivier, Madame Hoste, Marie van Houtte, Dr. Grill, Edith Gifford, Homère, Madame Cusin, Madame de Tartas, and Sunset. Bourbon: Mrs. Paul and Souvenir de la Malmaison. Hybrid Teas: Angeline Ginoiseau, Captain Christy, and Souvenir de Wootton.—P. U.

—The Rev. Dean Hole says in his delightful book about Roses that we must love Roses if we want to grow them successfully; but I fancy this correspondent thinks that they will grow in any jumbled-up fashion. The dead plants he speaks of will, I should hope, prove that he is wrong, and that he will be prepared to give them the attention they require; if not, the best selection of varieties in the world will not help him. Anyway, it is not pleasant to be told—as I have been before now—that the selection of Roses you made for me were a poor lot. Here, however, is a list of good hardy H.P.'s, that does well under ordinary favourable conditions: Earl Dufferin, General Jacqueminot, Charles Lefebvre, Ulrich Brunner, Captain Christy, Paul Noyron, Mrs. G. Dickson, Mrs. Jowett, Mme. Gabrielle Luizet, Prince Camille de Rohan, Hypelyte Jamin, John Hopper, François Micholon, Duchess of Albany, Alfred Colomb, Caroline DuRouch, and Countess of Rosebery.—J. C. C.

4611.—**White Roses.**—Although there are a good number of White Roses, there is not a wide range of choice for the purpose you require them. As a summer-flowering Rose the White Bath is unsurpassed in the purity of its colouring, which is paper-white. Blanche Moreau is an excellent perpetual Moss Rose, and sweetly-scented. Madame Plantier is also fragrant, but it must be allowed to grow into a spreading bush to do well. The pretty little Miniature Rose, Paquerotte, would be very suitable.—J. C. C.

—White Bath is the finest Moss Rose for your purpose; in addition to this I should choose the following three varieties: Souvenir de S. A. Prieux, Madame François Pictet, and The Bride. All are very sweet-scented and free-flowering; they are also of much the same growth as regards strength.—F. U.

4576.—**Plants and insects.**—Probably slugs are the enemies which have destroyed the Pears and Sowdowens. An excellent plan to trap these enemies is the following, which the writer has found most successful. Small tins, such as those used for cocoa (or old encans) may be placed in the ground, the edge level with the soil, and filled with milk and water or flour and water. Into these tins or encans the elings will crowd greedily, and in a few days they are full of the stain, when they can be taken up and fresh milk or flour and water supplied. Snails even will tumble into rather deep tins, but slugs are caught better in this way than in any other, as there is no necessity to go out late at night to catch them. A thorough dressing of lime will be beneficial to the soil when the spring arrives and soot should be used freely, but not stable-manure when there is a plague of elogs. Soot and lime should not, however, be used together for chemical reasons, but a dressing of soot may be given at any time with advantage.—I. L. R.

4508.—**Wooden labels.**—All the preparation wood labels require is to slightly char the parts which go into the soil by holding them for a short time over the flame of a lamp, and then rub a little white paint on the side which it is intended to write upon. (They say wooden labels may be bought much cheaper than they are sold at home. All seedsmen keep them.) The same may be said as regards stakes for tying up plants.—E. H.

GARDEN WORK.

Conservatory.

Ventilate at every favourable opportunity, but avoid cold draughts. Mignonette coming into flower must have a light position near the glass, and be watered carefully; in fact, all waterings should be done with judgment now. There is no better test than tapping the sides of the pots, and if in doubt after this test, lift the pot and try its weight. During winter the watering is the most important work. Some plants require more water than others. Among these things which require abundant supplies are Chrysanthemums, Gladioli, and Calceolarias. All Chrysanthemums should now be in a position where protection can be given on cold nights. Late blooms are more valuable than early ones; therefore the late varieties should not be hurried. Only shelter from frost is required in the case of late sorts. The early and late varieties should not be placed in the same house. The plants just opening their flowers will require a little fire, not only to keep out frost, but to expand buds, which will in the case of large, highly-fertile blooms, be even more injurious than frost. Liquid-manure may be given till the flowers are half expanded, and should then cease. Where a collection of hard-wooded plants are grown they should have a house to themselves, and only a little fire-heat used on cold nights, the ventilation being as perfect as possible consistent with the avoidance of cold currents. To do things really well the Pelargoniums should have a house to themselves also. In winter Pelargoniums require a light, airy position, with a night temperature of 50 degs. or so, so as to keep the plants growing slowly all winter, shifting into the blooming pot not later than February. Zonal Pelargoniums will soon be very bright, but it is useless expending a good winter bloom without a genial warmth from fire-heat. There must be heat enough to admit of air being given during the day. If the damp settles on the blooms the fire is soon got wrong. When all the different families of greenhouse plants are cultivated in one house, great care is necessary, both in watering and ventilating, and even then the result cannot be so satisfactory as where several smaller houses can be given to them to permit of their being grouped according to their individual wants. As soon as all the plants are housed, and are settling down a bit, it will save trouble hereafter if a moderate fumigation of Tobacco is given. It will give the few insects which are probably in the house notice to quit. One smoking will do as much good now, when possibly the insects are very few, or even their presence may not have been noticed, than two or three fumigations will do later on, when the warmth and the changed conditions of growth has brought forth numbers of insects. Put up *Spiraea japonica*, *Dryas* (sp. variable), and other hardy subjects for forcing during winter. For the present they may remain in a cold-house or pit. The soil and other boxes which have been prepared for forcing will be better in a cold pit before frost comes.

Stove.

Eucharis Lilies will either be in flower, or the spikes on the point of starting. The flowers are more valuable in winter than summer; therefore the largest number should be worked with that object in view. After the bulbs have been raised an oiled cover for a few weeks, the application of a genial heat, say about 65 degs. at night, with weak liquid-manure applied twice a week, will soon start the spikes. Though stove plants may be grown without bottom-heat, still, a plunging-bed is a valuable adjunct to the stove in forwarding such things as *Eucharis*, *Gardeula*, &c., and the atmosphere of the house is always more genial where there is a speedy fermentation of leaves or tan going on than when the necessary humidity has to be kept up by throwing water down. Stove plants require more atmospheric humidity than any others. A dry heat would soon have a ruinous effect upon stove plants. The practical cultivator, when he puts his head inside a plant-house, can tell in an instant if the conditions of healthy growth are present. Long experience teaches this amongst other things which the novice has to find out by watching thermometers and other instruments. The night temperature of the stove need not exceed 65 degs., and on cold, frosty nights 60 degs. will do no harm. There will be those who say that if a cover of some kind can be improvised, where the house is fitted with blinds, instead of taking them down in winter let them remain, and roll them down on cold nights. Even if they wear out faster, the saving in fuel will more than pay for it, and if on a cold night the ere gets low towards sunrise in morning the plants will be quite safe when the glass is covered. Those who have never tried covers in winter will have their eyes opened to the advantages in a very short time.

Orchard-house.

Most of the late Peaches will be gathered now, and the fruit can be set outside, and the house used for other purposes. This house is generally used for Chrysanthemums, and by the time the Chrysanthemums are over the tree will want to come back. Any fruit-trees which require re-potting should have a shift at once, whilst there is still some little force left in the leaves. Surround the pots with long, dry litter before severe frost comes.

Cyclamens and Chinese Primulas.

These plants do well together. Both like when in bloom a genial temperature of 50 degs. or so. A light position is also necessary, and there must be free ventilation, or the flowers will damp. Cyclamen bulbs must not be buried in the soil, or the leaves and flower-stems will damp off. The largest half of the bulbs should be above the ground level, so that the leaf and flower-stems may stand clear.

Tree Carnations.

These plants do well together. Both like when in bloom a genial temperature of 50 degs. at night if they are to flower well. They are not satisfactory in a cold-house. Only a limited number of the Tree-Carnations will flower freely in winter, and there must be strong plants before winter sets in. Miss Joffine Improved is one of the best. Though the rubers of Tree-Carnations have given us dwarfier habited plants, it is a question if they flower any better in

winter than the old sorts grown forty years ago. There used to be no difficulty many years ago in having plenty of Tree-Carnations in winter. The flowers were rougher in outline, but they were quite as sweet, and even more numerous than the modern flowers. Winter Cheer is a good variety for winter, and the other day I saw a large quantity of the Marguerite Carnation just coming into flower, proving these are useful for winter blooming, but I do not think they will stand much winter weather. The flower-buds should be prominent by autumn, or by the time they are taken indoors. These will be very useful in the amateur's greenhouse.

Bulbs for Forcing.

should be potted at once. Hyacinths, Tulips, Freesias, and Narcissus are all useful. Plunge over the rims in Cocoon- fibre outside for six weeks to make soot—at least, all except the Freesia should be plunged. The latter will be better started in a cool greenhouse, if covered with anything the growth comes weakly.

Window Gardening.

Do not buy *Bonardias* which have been forced into bloom; in fact, any plants taken from a higher temperature than 60 degs. will be weak, and will be in poor condition. The most useful plants for winter decoration are *Aspidistra*, *Kentia* (in the way of Palms), *Aralia* *Strobilifera* and the variegated variety, *Cyperus alternifolius* and *O. distans*, *Dracena indica*, and other green-leaved sorts. *Ficus elastica* does well. Flowering stuff can be introduced as required; but with care the foliage plants named above will be more or less permanent.

Outdoor Garden.

All tender plants must be placed under cover, as there is risk of injury to leaving them exposed now. Questions bearing upon the keeping of tender plants in cold frames have often been asked, and though it would hardly be right to say the thing could not be done yet, the result was so often unsatisfactory that it was hardly worth the attempt to do so without some artificial heat. If the plants survived, they came through the ordeal so much weakened that it took them half the summer to get over it; but though Geraniums are difficult to keep without artificial heat, those plants which may still be propagated may be kept in a cold frame quite safely. *Calceolaria* cuttings put in now in a cold frame will make nice plants next spring. *Pentstemon* and *Antirrhinum* in assorted colours, white, yellow, and crimson, will root freely from cuttings planted in boxes in a cold pit. I have a very numerous number of *Geraniums*, advertised to the value of the *Tobacco* *Sergina* to those who have no means of keeping tender plants in winter. The tubers may be lifted, packed in boxes of sand, and placed in the cellar where the frost cannot enter, and kept there till spring. These are very bright and effective, and may be easily had in assorted colours of white, yellow scarlet, and pink, and these in association with masses of early flowers will make a very bright and interesting garden. It is not worth anything for fuel or pot. In some time now in getting in early-flowering bulbs, such as *Snowdrops*, *Crocuses*, *Daffodils*, &c. A good deal, too, may be done to make a garden beautiful with dwarf shrubs, Tuled *Panicles*, and hardy annuals, all of which should be planted as soon as the tender things are cleared. Prepare sites for Roses by trenching in plenty of good manure. Lift *Dahlias* and *Gladiolus* roots when out of frost.

Fruit Garden.

The principal work for the next week or two will be gathering the late Apples and Pears. Do not be tempted to gather the best late sorts too early, if they are required to keep in a fresh firm state till their allotted time. There are plenty of indications to guide us in gathering late fruit, but the best hint is given by the tree itself. When the fruit next readily from the tree it is time to gather them in. In this season of plenty the trees will probably be cleared at one operation, but in small gardens more might be made of the fruit—i.e., the season might be prolonged if the gathering of the best kinds of Pears was spread over two or three weeks. I have lengthened out the season of *Marie Louise* considerably by gathering the fruit first of all from the sunny side of the tree, leaving the other to hang ten days or a fortnight longer. Autumn Pears are very often gathered in a hasty way. If the crop is large and certainly be considerable waste. I have often heard the remark, "What a shame to let these beautiful Pears decay!" But 'twas in to help it where the sale or consumption is not sufficient to clear them off whilst they are good? A Pear may be sound and good apparently one day and a mass of interior decay the next. The late-keeping Pears such as *Doyenne du Comice*, *Winter Nellie*, *Bergamotte d'Espere*, *Glou Morceau*, *Burré Rance*, and *Ne Plus Meurle* do not decay so rapidly when they are ripe, and therefore the season can be prolonged. Both *Strawberries* and *Raspberries* are, in many gardens, anticipating the next year's crop this season. Some buds of early *Strawberries* that were injured by the hot weather are now bearing very freely. This heavy tax upon vigour should be met by giving additional support as soon as the fruits are gathered in the shape of rich top-dressings of manure.

Vegetable Garden.

Good vegetables are more plentiful now than they have been all the season. Late Cauliflowers are very good, and though there has been a little frost, *Spaghetti* *Turneps* are still bearing freely, but late Peas have in most gardens been a failure. The summer was so exhausting; even the Peas sown late and kept moist by watering did not do well. But root crops have been better than the promises. Beet-root, Turnips, Onions, and Carrots where proper attention has been given have turned out much better than expected. Where it was impossible to water the crops the frequent use of the hoe has been very beneficial; by keeping an inch or so of loose soil on the top the moisture has been kept in the land and the effects of the hot sunbathing mitigated. If early Peas are sown now in pots or boxes, the green tops, when about 4 inches high, will come in useful for flavouring soups. Take up *Beetroots* before frost comes, and secure *Cauliflowers* turning in. In some way, simply breaking a leaf over the hearts or tying the leaves up in a cluster over their hearts will save them from several degrees of frost. Late Broccoli may be laid down with heads to the north. Heeling, it is sometimes advised, but this is not a very good plan. Lifted out of the ground, the exposed soil is removed from the north side

* In cold or northern districts the operations referred to under "Garden Work" may be done from ten days to a fortnight later than is here indicated, with equally good results.

of the plants, the spade is then thrust in on the south side, and the plant is heeled over so as to be on its side, a spadeful of soil is placed on the stem to shelter, and this leaves a hole for the next plant to fall into. It is not a long or a difficult job, and if we get 20 days of frost during the winter it will save the Broccoli crop. E. HOSBAY.

Work in the Town Garden.

There has, fortunately, not been enough frost so far to cut off or injure the Dahlias, which consequently continue to make a nice display of colour. With plenty of these, Chrysanthemums of the hardier varieties, Michaelmas Daisies, Japanese Anemones, and Torch Lilies (Tritomas) in town garden need be other than gay during the autumn months, and, as I believe I have remarked before, curiously enough all these hardy autumn-flowering subjects thrive better in a smoky atmosphere than almost any others. Verandas of the shrubby section are equally suitable and successful, and are flowering freely, and even the pretty and fragrant white-flowered Tobacco (Nicotiana glauca) continues to push up its charming blossoms in warm and sheltered spots. Referring again to the subject of Dahlias, I have come to the conclusion that on the whole, and for general decorative purposes, supplying out flowers, &c., the Pompan class is decidedly the most useful and effective. The huge "show" kinds are out of it altogether, either for cutting or display, and beautiful as many of the "Cactus" flowers are individually (the newer ones in particular), in most cases they are not produced with sufficient freedom to compare with the pretty little Pompan. The colour of these last, too, are now very varied and rich, the blossoms are neat and nice for cutting, and the habit of the plants is dwarf and bushy in the extreme. By far the freest and best of the Cactus tribe for cutting—at least, where quality is an object—are the brilliant sweet-flowered Fire King and the deep crimson Cocklehead. Where a large conservatory has to be furnished a number of Dahlias grown in large pots are of the greatest value in the autumn after frost has set in, and form an excellent contrast to the Chrysanthemums. Hardy perennials of all kinds may be safely planted now—at least, in suburban districts or small towns, where the

Those who are bothered with wireworms should grow their Carnations in large pots. The plants always do well in pots if kindly treated, and with ordinary care the wireworms can be kept out. Transplanted Tripoli Onions in rows 12 inches apart, 6 inches from each other in the rows. The ground had been well prepared, and then made firm. Onions are sown to grow in thick-soaked in loose soil, Gathered Apples and Pears, also Cook's Golden Drop Plums. The latter will keep a long time late on a shelf in the fruit-room. Peaches on walls have done well this season. Still gathering a few late kinds, including Sea Eagle and Seiway. Dig Potatoes. This work is pretty well finished now. In preserving these for winter use they always keep better covered with earth enough to keep out frost. Then in buildings the quality is so much better. No matter how securely Potatoes are covered when stored in buildings, they lose flavour as the season rolls round. Took up and stored Beetroot. I find these keep best when covered with dry soil. Do not use a knife in trimming these. A wounded surface will injure the colour—or rather the colour will hold out in the cooking. The leaves may easily be twisted off, and after the roots are dried in the sun, packed in dry earth or sand, and cover with straw and earth. If stored in a cellar they should be packed in sand. Gathered all the Tomatoes still on the plants outside and placed on a stage in the vinery. They will ripen out in due course. The fruits of one or two plants of more than average fertility have been saved for seed. It is difficult to keep stock quite true if more than one kind are grown in the same house. Cut off the tops from Asparagus beds. They will do no more good now. The plants intended for early forcing have had the tops removed some time ago to ensure early ripening.

FLOWER GARDEN DATURAS.

Among the numerous plants available for garden decoration, but which are mostly conspicuous by their absence, several species of annual Daturas occupy a prominent place. The genus includes five or six species, possessing some

finally planted out where they are to stand. They need ample space for their full development, and should be grown in light sandy soil in preference to such as is of a heavier nature. But few gardens exist where appropriate situations for one or more of the species may not be found, and in most there is abundance of room for all those here named. Most of the Daturas thrive well in the neighbourhood of the sea. G.

FERNS.

THE HAY-SCENTED FERN (LASTREA ÆMULA).

SOME readers signing themselves "Cockneys"—which is, I suppose, because they live in the County of Middlesex, for scarcely the place from whence this letter is dated is not within the sound of Bow Bells?—tell me they have been in Devonshire and collected some Ferns which they intend to ask me to name for them, which I shall do with a great deal of pleasure if I can; but they send this one, saying: "That it has a very powerful odour of new hay;" which is quite right, and this alone makes it a very desirable plant to cultivate in the home rockery or rookery. It may be easily grown in any such a place. Now I do not want to know what part of the County of Devon my Cockney friends found this plant, and I should advise them to keep quiet about it or perhaps it may become exterminated by the rapacity of Fern-hunters and dealers, such as have denuded our country places round about London of every bit of greenery in the shape of a Fern, and having marked a certain number of plants for your friends who are resident there to send you, this is as it should be, and the spot does not become stripped of the species. This is a very graceful Fern, and one that has a wide distribution over the British Islands, being found in England, Ireland, Scotland, and Wales, and whilst one may search for it in one place, and never find a trace of the plant, it may crop up in abundance when little thought of. The plant is of tufted growth, and it sends up fronds to the height of about 18 inches and 2 feet, and about 6 inches or 8 inches in height. These are deltoid in outline, three times divided, having a somewhat crisp appearance, and powerfully scented like new made hay, and by which it may be readily distinguished. The plant, although so widely distributed, has broken less into varieties than other and closely allied species; for I have only seen about two distinct varieties; but, of course, there may be more known, but I never remember to have seen but the one called prolifera, and another named cristata; both these varieties, as well as the typical plant, make exceedingly beautiful plants in pots, and where my readers have no convenience for growing them in the open ground I would strongly urge upon them to try pot culture for this plant and its two varieties. They should be well drained, and the soil best suited for them is loam and peat made sandy, being unlike the majority of our native kinds of Buckler Ferns, which are deciduous. This is nearly an evergreen, and hence its utility as a pot species is all the more strikingly exemplified. J. J.

Flowering shoot of Datura meteloides.

soil is fairly light and the drainage good; but in very smoky places, as also where the soil is heavy or damp, it is safer to wait until the spring. Some of the beds that have been cleared of summer bedders, annuals, &c., may be filled with Chrysanthemums and dwarf evergreen shrubs, both grown in pots and plunged, and if desirable, bulbs may be planted between. Insert cuttings of Pentstemon at once; also of the shrubby Calceolarias, if early-flowering pot plants are wanted next season. By inserting the cuttings early, and giving them a slight warmth through the winter, they are much more forward. Seedling Tuberosa Begonias and Glaxinas are flowering finely in a warm-house now. B. C. R.

THE COMING WEEK'S WORK.

Extracts from a garden diary from October 7th to October 14th.

Filled several frames with Calceolaria cuttings, young shoots about 3 inches long being chosen. They were dibbled into a bed of loam 3 inches apart. Very little protection is sufficient to keep Calceolarias safe when planted in a bed in a frame. In pots or boxes more covering will be required. A little dry Fern or litter scattered near the frame when frost sets in will suffice. The soil in which the cuttings are planted should be kept in a moist condition, but not saturated. The disease from which these class of plants suffer in summer is often caused by extreme dryness in winter. Busy clearing flower-beds and filling up with bulbs, Viola, hardy annuals, shrubs, &c. Took up Dahlias and Gladioli. If either of these are exposed to frost the roots perish. I once lost a nice collection of Gladioli through leaving them too long in a potting-shed. A sudden frost of unusual severity reached the Gladiolus bulbs and destroyed the lot. I am not likely to forget this. Started a lot of French Beans in a warm-house for winter bearing. At this season 6-inch pots are used—five Beans in a pot. The pots are not more than three parts full when the Beans are covered. This leaves room for earthing up later on. The best variety for forcing, I think, is No. Plus Ultra. Finished planting out Carnations and Pinks. A few of each kind are potted up, and will be wintered under glass, and afterwards potted into large pots—two plants in a pot.

claim to notice; but those which more especially merit attention are—

D. CERATOGAULA, probably one of the best known. It grows from 2 feet to 3 feet high. Its sweet-scented, trumpet-like flowers are produced from the axils, the corolla being often 6 inches in length and 4 inches or 5 inches across the limb, which is white, tinged with violet-purple externally and at the angles. The flowers, both of this and the following species, expand towards the end of the afternoon and close the following morning.

D. METELOIDES, a native of Texas, of which a figure is here given, differs from the preceding in its broader foliage, as well as in its somewhat large flowers, in its calyx-tube not being split on one side, and in the capsule being epiny; the limb of the corolla is usually more completely suffused with pale-violet.

D. FASTUOSA, if less remarkable for the size of its flowers than the species already referred to, has, nevertheless, merits peculiar to itself. Even the single form of this plant, which in the type is creamy white on both exterior, yields a very effective variety with the corolla of a deep-violet externally, the interior being white, as in the type. The most striking forms of this species are those bearing double flowers, the primary corolla having a second, and sometimes a third, arising from its tube, all perfectly regular in form, and often parti-coloured, as in the single variety with violet flowers. The culture of these Daturas offers no especial difficulty. Fresh seeds are readily raised in an ordinary hot-bed, and the young plants should be planted out singly in pots while small and

4622.—Mealy-bug.—Mealy-bug on any plants which cannot be at once burned is a terrible pest, and it is absolutely ruinous on Grape-Vines, spoiling the fruit and making it quite unfit for use. As soon as the Vines are pruned burn the prunings, and clear every plant out of the house, except the Vines. Then make a solution of Gishurst Compound by dissolving it in boiling-water at the rate of 6 oz. or 8 oz. to the gallon. When cool enough to bear the hand in brush it well into every part of the stems of the Vines, going over them twice so that none may be missed. Then wash every bit of paint with the same mixture, using a brush or flannel, and whitewash the walls with fresh lime, and if the borders are inside take off 3 inches off the top and fill up with good loam and manure. As soon as the buds begin to move in spring keep a sharp watch for the first bugs, and though there may not be many there will probably be some, which, if allowed to remain, will soon fill the house again.—E. H.

4623.—Spiraea japonica.—Better leave the Spiraea another year before forcing. You may pot up in October next year.—E. H.

TREES & SHRUBS.

THE BUSH HONEYSUCKLES.

THESE are very good shrubs, flowering in early summer, and known by botanists as *Dicranellæ* or *Weigelas*, which are often crowded into a shrubbery, where it is impossible for them to make the free, graceful growth, laden with flowers, characteristic of well-planted examples. They are also known by the popular name of Bush Honeysuckles, and the long list of varieties embraces flowers of many shades of colour. They are essentially shrubs for the amateur—the growth is quick, and healthy hedges may be looked for even under apparently depressing circumstances, as in ordinary soils and positions they make great headway and bloom profusely. In the month of June every shoot is covered, almost hiding the leafage, and a scattered succession is maintained throughout the summer. I have seen splendid bushes, the branches touching the ground and full of vigour, in soils and situations where one would think it was scarcely possible for such beautiful things to thrive. But the choke-middle shrubbery is not the place for the full beauty of this shrub to be revealed; it is better either as a separate bush, standing out boldly on the lawn and displaying its full gracefulness, or massed together in a bed, as I saw a few days ago in a Middlesex garden. The variety planted was *Abel Carrière*, the flowers crimson, deepening to a more intense colour in the buds, and every shoot was weighted down with the burden of blossom, the growth spreading about in its own characteristic and charming way. The types of the *Weigelas* are *W. floribunda*, *W. rosea*, and *W. grandiflora*; then we have such kinds as *W. hortensis*, and its pure white variety *nivea*, a very beautiful and free-flowering shrub. The species are natives of China and Japan, and have given rise, through crossing, to a numerous progeny. Those that have emanated from *W. grandiflora* are the more useful, by reason of the flowers being bolder, but from the other types have also come many valuable kinds. One of the best is *Abel Carrière*, to which reference has been made already; its flowers are of fine colour, and very showy when in contrast to the Grass; and worthy also of mention are: *Lavallei* (an excellent variety, the flowers deeper than in any other *Weigela*, and red-purple in colour), *Van Houttei* (red), *Hendersoni* (conspicuous for its compact habit and flowers of crimson tone, paler outside), and *John Standish* (which has large flowers, also of a reddish colour). The species *D. rosea*, introduced by Fortune from China, and certainly one of the prettiest things he sent to England, is a shrub of great elegance, and very charming when its rose-coloured flowers are in full beauty in the month of June. Its compact, yet by no means formal growth adapts it for filling a bed. Then we have such beautiful things as the later-blooming *W. amabilis* and varieties, of which the following are amongst the best. *Desboisii*, very handsome, the flowers deep rose in colour; *Grünwegeni*, one of the most attractive of all, the colour rose, with occasional streaks of red; *Gustave Mallet*, rich red, and *Mona Lemoine*, which displays varied shades of rose. Although *W. hortensis nivea* is a beautiful shrub, the variety named *candida* is finer, easier to grow, and more satisfactory. The habit of *candida* is strong, and will attain in the course of time ample dimensions, the flowers first appearing in June, and by reason of their purity and profusion create a pretty picture, especially if placed against dark leaved things to throw up the white. As in many of the varieties, the shrub continues to bloom more or less until the autumn. *Nivea*, on the other hand, is not so stiff as regards growth, but does not make such quick progress, the flowers white and produced freely during early summer. There is also a variety named *rubra*, which, as its name suggests, has flowers of a deep-red colour, but this is most pronounced in the buds, the red tone disappearing when they are fully expanded, disclosing almost a pure white centre. There are several variegated *Weigelas*, but I do not care for such things unless the colouring is distinct and decided, and the shrubs are planted with extreme caution. Too many variegated shrubs in a garden produce a sickly, undesirable effect, but I may mention the following as of recent introduction.

is one of the best, the leafage rich golden colour, and retains its character through the summer months. It is not every variegated shrub that shows this essential trait, frequently when the first beauty of the foliage is over displaying objectionable tones. A dwarf variety is called *nana variegata*, the leaves distinctly variegated with a silvery colouring, the flowers almost white, and this silver shading is not obliterated under a summer sun. Although the *Weigelas* require very little of what is commonly called

Flowers of a Bush Honeysuckle.

cultivation, there are a few points that must be attended to, if vigorous, healthy bushes are desired. When each bush is allowed to grow in its own way, unfettered by neighbouring things, it will rise many feet in height, ten or twelve, even more, and it is under these conditions that one sees their gracefulness and distinctive charm. In ordinary soils it is well also to give an annual top-dressing to maintain their vigour, and quite as important is the removal of weakly growths. I was looking the other day at some *Weigela* bushes split through a crowd of shoots preventing a sturdy development of the branches, and the flowers were neither so large nor so profuse as would otherwise have been the case. It is therefore essential to prune vigorously to retain the stronger shoots. When a good selection of *Weigelas* is made, and the shrubbery carefully grown, there are few things in the garden of greater beauty in the early summer months. V. C.

4625.—**Shrubs in flower-bed**—If you had given the dimensions of the bed it would have been more easy to advise you. For filling fair sized beds the hardy *Azaleas*, *Deutzia gracilis*, *Hydrangea paniculata grandiflora*, *Kalmias*, *Permettya*, *Philadelphus* (or *Mock Orange*), *Veronica Traversii*, *Viburnum plicatum*, or the Chinese *Guelder Rose*, and *Weigelas*, may be mentioned. The two best subjects are the *Viburnum* and hardy *Azaleas*; and if you care for the *Mock Orange* select the dwarf kinds, such as *Philadelphus microphyllus*, which is a quite dwarf shrub, and laden with pure white flowers in summer. You must not have too tall things for the bed. The *Hydrangea* is splendid for beds, and produces very large heads of flowers. One of the most pleasing beds I have seen this year was composed simply of this, with a deep-purple *Tufted Pansy* as a groundwork. Even in small beds delightful effects may be obtained. The *Veronica* is rather better when isolated than grouped in a bed. The *Viburnum* mentioned is quite distinct from the common *Guelder Rose*. It is dwarf, and the flowering shoots are wreathed with creamy-

white flowers, which are in bold contrast to the deep-green wrinkled foliage. All these things may be planted in good garden soil at this season, and are perfectly hardy, although in very hard winters the *Veronica* gets out about with frost. As regards perennial plants there is a wide selection. You will do well to get the *Tufted Pansies*, such as have been mentioned recently in *GARDENING*. They are remarkably free, beginning to bloom in early summer, and maintaining a display until quite the autumn. There are many beautiful kinds, the colours varying greatly, from white to almost black, so intense is the shade. These will do for the surface of the bed. In one bed you can have a white variety, and in the purple, light-blue, or whatever shade you care about. Or you may have an edging of one variety and fill the remainder of the bed with a kind of another shade—of course, in suitable contrast. *Phloxes*, *Lobelia fulgens* is variety, *Carnations*, *Pinks*, the beautiful early autumn-flowering *Anemone japonica*, its flowers pure-white, in the variety *Honorine Jobert*, but rose in the type; *Erigeron speciosum*, which blooms more or less the whole summer; *Aster acris* or *A. Amellus* for the autumn, two dwarf kinds, very beautiful in beds, and a mass of bloom; *Lupinus polyphyllus albus*; spring-flowering bulbs, such as *Daffodils*; and a host of other things might be raised, did space permit. If you have shrubs, such as *Kalmias* and hardy *Azaleas*, plant *Lilies* between; *L. tigrinum splendens*, for late-blooming; *L. auratum*, for late July and August; *L. candidum* (the *White Madonna Lily*) for June; and *L. speciosum* or *L. lancifolium* for September. Of course this entails more expense than plants with hardy things alone. If you plant *Azaleas* you must make a peat bed, such as was described in *GARDENING*, p. 427; and the *Kalmias* also require a peaty soil. I should think, judging from your description, that *Gladioli* would succeed well. Try *G. bronchleyensis*.—C. T.

4601.—**Paring and burning turf**—If the ground is to be cultivated subsequently, I strongly advise you not to burn the turf, but simply dig it in just deep enough to kill the Grass. To burn turf, except with the sole object of destroying it, is mere waste of valuable material, as when decayed it forms the best medium possible for the healthy growth of plants of all descriptions. Burn all rubbish, &c., on the ground by all means, but not the turf; it is for potting and similar purposes. I have sometimes just charrd it in order to kill the Grass and save time. Turf is easily and quickly parod by means of a proper turfing-iron; but to prepare Grass land for cultivation, the best way is undoubtedly to take off the top spit from a space about 3 feet wide right across the ground, and wheel it to the farther end; then just turn over the second "spit," adding manure, &c., as required. Then dig up and add throw on to the first space, or "trough," the top spit from the second, placing it Grass side down, and so on throughout. If this is done at any time during the autumn the ground will be in first-rate condition for cultivation by the following spring.—B. C. R.

4636.—**Treatment of Begonias**—Some *Begonias* are decidedly prone to drop their buds in a very annoying and unsatisfactory manner, but each should be the exception rather than the rule. From what you say I opine that the soil you employed was too rich, and also that too much water was given to the plants. They ought also to have been shaded from the sun, which has this year been altogether too much for plants of this kind under glass. Try again next season, using sandy loam and leaf-mould only, shading from hot sun, and watering only as required.—B. C. R.

4616.—**Packing Lilies**—Lily bulbs will keep in good condition a long time packed in Cocoa-nut-fibre in a cool place. I planted out some good, sound bulbs last April, which had been packed in Cocoa-nut-fibre all winter; but the *Old White Lily* (*L. candidum*) is an early grower, and should, if possible, be planted in pots.—E. H.

—As these plants begin to make fresh roots in the autumn it is injurious to keep them out of the ground until the spring. As many as possible should therefore be potted as soon as the stems die down, and, if necessary, planted out from these in the spring.—B. C. R.

4505.—**Making leaf-manture**—Place the leaves in a heap in any out-of-the-way and rather damp spot, and let them remain undisturbed until they become sufficiently decayed. Any attempt to hasten the process will be unavailing. Do not buy them.—B. C. R.

FRUIT.

PLUM ANGELINA BURDETT.

In reply to queries about this Plum, the tree is very hardy, a good bearer on bush, pyramid, or standard, and is worthy of a good position on a wall or in the orchard-house, and, having smooth shoots and leaves, it is not subject to green-fly. Add to these constitutional qualities the following points—for after all the proof of the Plum lies in the eating—and I think those who have not given it a trial will at once add one or more trees to their selections: Fruit above medium size, roundish, oval, and marked with a deep suture, especially near the stalk. Skin thick, dark reddish-purple, closely covered with small brown dots, which show through the deep-purple bloom. Stalk short, firmly set, and holding the fruit long after it is ripe, sometimes until it shrivels. Flesh yellowish, rich, juicy, parting freely from the stone; fit for use early in September, but grown in the old orchard-house or upon wall-trees the fruit is greatly improved by hanging until, like Golden Drop, it shows signs of shrinking. Viewed from a commercial point, the Plum, next to the Apple, is generally accepted as our most profitable indigenous fruit; but the varieties being so numerous, soil, situation, and use should be well considered before market culture is entered into. For private use the motto should be few varieties, these the very best, and plenty of duplicates. Taken in alphabetical order, and following Angelina Burdett, a most delicious variety for a pastels dish when cooked, as well as the dessert, we have the little-known black Plum named Belvoir, admirably adapted for a wall, as it hangs in good condition until the middle of November. Passing Gorse's Nota Beuo, a Canadian Plum, Damas de Mangeron, an Italian Damask, good for preserving, we come upon Kirke's, if not the best, certainly the best-known and most popular purple dessert Plum now met with in every good garden, and almost invariably used by exhibitors, making a most tolling dish when grown against a warm wall or in the orchard-house. A companion to this, but much earlier, is the Montfort, a most delicious variety of Royal Hative, ripe about the middle of August, and probably the best very early orchard-house or wall Plum in cultivation. The well-known froststone Prince of Wales, we learn, will soon be superseded by the Sultan, a clingstone, having a formidable rival in Belgian Purple, an immense cropper, and good for dessert, but as a culinary Plum one of the very best for cooking and preserving. Purple Gage or Reine Claude's Violotte, a familiar Plum, is considered one of the best, especially when it begins to shrivel, but although a freestone, it does not, in my opinion, come up to Late Rivers, a Sawbridgeworth seedling, ripe in October, and keeping in good condition until the middle of November. The latter requires a good west wall, and deserves extensive cultivation as a companion to Coe's Golden Drop for coming in late in the orchard-house. Although all the varieties of Plums fruit profusely when grown in pots, none but the very best should be selected for orchard-house culture. Therefore, considering that there are six or seven sections, including the Gager, a heat in themselves, to choose from, the contribution from the Nectarine Plums may include Angelina Burdett, Kirke's, De Montfort, Purple Gage, Woolstan Black, and Late Rivers. Pines of Wales, Belgian Purple, and Sultan are admirably adapted for growing as standards.

fruit often weighing 20 oz., the quality is fairly good, and is ripe toward the end of September or early in October. Maris Louise is perhaps regarded as the best Pear for general purposes in cultivation, as it possesses all the qualities necessary; in use during October and the early part of November. Winter Nellis and Olou Moreceau are capital winter Pears, coming in in December. A four-year-old horizontal-trained tree would be the best for the purpose, as a tree of that age would give some fruit the second year of planting. Trench the soil fully 18 inches deep where the tree is to be planted, but do not cover the roots more than 3 inches deep with soil. Over this lay a 2-inch thickness of half-rotted horse-manure to preserve the roots from frost and to maintain them in a cool, moist state during the summer. Directly the leaves fall is the best time to plant fruit-trees of any kind. Do not fasten the trees to the wall until the spring; the soil will have settled down to its natural level by that time. Choose a dry day for planting, so that the soil mixes well with the roots. It is not wise to add much manure to the soil when planting; if the soil is poor give a little.—S. P.

4631.—Treatment of fruit-trees.—The proper thing to do would be to root-prune all but the standard tree, and at the same time to cut back the young shoots two thirds of their length, but it will never do to prune the branches so hard and not the roots. If you can undertake to root-prune skilfully do so by all means, but it must not be done in a haphazard fashion. If you can devote time and skill to the work it will pay for doing so; if not you had better prune the bushes very moderately, and root-cut altogether any of them that are not satisfactory, so as to give you more room.—J. C. C.

— If the trees have been growing in their present position some years and bear annually good crops of fruit, they can be kept to their present size by cutting away all the new shoots every year. A few of the outer branches may also be shortened where they are too long, cutting off at least 1 foot all round. It may be wise also to remove a few of the branches from the centre of each tree, if they are at all crowded, selecting the weakest for removal. All the sorts of fruit named will bear pruning as

any fruit-tree in winter when the leaves are off and the buds dormant, and at that strength every insect touched with it will die.—E. H.

4640.—Grape-Vines in a greenhouse.—Cracked berries have been pretty much in evidence this season, especially in houses which are devoted to flowers as well as Grapes. The berries crack from more than one cause. Dryness at the root, followed by a sudden watering is, however, the most frequent; but in your case I should say it was caused by a sudden change in the internal temperature, which caused a contraction of the skin. The want of colour in the berries is through leaving so many bunches to ripen. Reduce the number next year one-third.—J. C. C.

4912.—Clover-seed and Straw-berries.—White Clover in a Strawberry-bed is a strong, deep-rooting weed, and nothing else, and under no circumstances should it be sown if good fruit is required. It is a very easy matter to mulch Strawberry-beds with long stable litter in April, and by the time the fruit begins to colour there will be a clean bed for the fruit to rest upon. Doublecropping of the kind named above will not answer.—E. H.

— The idea of growing Clover amongst the Strawberries is too absurd to entertain for one moment; not only would it interfere with the Strawberry roots, but it would rob them of nutriment as well as moisture. Plant Strawberry runners at once on well prepared land. That which has borne a crop of Potatoes will answer well. Have the rows 2 feet apart and the plants eighteen inches distance from each other. Plant Vicomtesse d'Aricart de Thury and Sir Joseph Paxton as maincrop varieties, with a few of Waterloo for a late supply. Keep the soil clear of weeds and nip the runners off the plants as fast as they grow. When the blooms expand spread a thin layer of clean straw over the ground underneath the plants; this will keep the fruit clean and arrest to some extent the evaporation of moisture from the soil also.—S. P.

4623.—Vines in a cold-house.—Open all the ventilators, doors, &c., so wide and fully as possible, and keep the soil barely moist—neither really dry or at all wet; any young growths or leaves should be strictly removed. Continue this treatment throughout the winter,

A dish of Angelina Burdett Plums.

4603.—Pear for a wall.—Emile d'Hayes or Doyenné du Caen. The former is the earlier, ripening in October, a very heavy cropper, and easily grown, while the latter ripens a month later, and will keep till Christmas, but requires rather more care. The flavour of both is unsurpassed.—B. C. R.

— Maris Louise is a general favourite, Doyenné du Comtes is late but equally good, and there are few better Pears at Christmas than Olou Moreceau, and this will pay on a wall in a good aspect.—E. H.

— It all depends what time of the year the Pear is required fit for use in training a sort. Williams' Bon Chrétien ripens in August, is a good cropper, and is generally regarded as one of the best. Louise Bonne of Jersey is ready for use during September, and is all that could be desired both for crop and flavour. Pittaston Duchesse is the largest kind in existence, single-

suggested. Directly the leaves fall pruning should be done, or indeed before they change colour, as there is no need to wait till then.—S. P.

4605.—Early Vines.—Forced Vines should be pruned as soon as the leaves are falling; there is no necessity to wait till all are down. Very few Grape-growers plant Vines nowadays unless insects are present, and even then I have as much faith in a strong solution of Gishurst Compound used warm, and brushed well into all the crevices as anything. A solution of Gishurst Compound (6 oz. to the gallon) may be used on

only closing the house in severe frost or storm. Early in February the Vines should be pruned, but if the weather is mild do not bury them into growth (by keeping the house close) until all danger of severe night frosts is past. Growth should recommence in March, and a thick bed to draw down over the roof on frosty nights would be a great help. Three of the best Grapes for a cool-house are Foster's Seedling, the Buckland Sweetwater, and the old Black Hamburg. Plant in March.—B. C. R.

— Vines without fire-heat have done well in sunny situations this season, and as the wood is

well ripened, the best treatment is to leave the ventilators open night and day and prune when the leaves fall. I believe in early pruning. Whether the Vines are forced or grown quite cold the house should be closed when severe frost comes, and at other times during winter ventilated freely. If the inside borders are dry give a good soak of liquid-manure; it will moisten and enrich the soil. The best Grapes for cold-house are Black Hamburgh and Black Alicante and White or Royal Muscadine. Foster's Seedling does well in a cold-house, and I have also ripened Golden Queen in a cool-house, the bunches being large and full.—E. H.

4632.—**Winter Pears.**—A cool, moderately dry room or cellar is the best place to keep fruit of any kind in; no more heat is required than will keep out frost. The fruit should be spread out in a single layer, either on the floor or on shelves, using neither straw nor sedge else to lay them on. If, however, a boarded floor or shelves are not available, clean straw is the best material to lay the fruit upon. If the room can be darkened so much the better. After the first two or three weeks but little air will be required. If it is not practicable to darken the room, cover the fruit with two or three sheets of newspaper; this will answer the purpose very well.—S. P.

4607.—**Apple-trees in bloom.**—This is a common occurrence this year. The buds which are flowering now will not flower again next year; but all the trees I have examined have still plenty of unstarted buds, so the chances are it will not seriously interfere with next year's crop. If one-tenth part of the blossoms which a fertile Apple-tree produces are there will be Apples to thin off. At the same time, the blossoms which are now produced had better be rubbed off.—E. H.

This is a common occurrence this season, owing to the exceedingly hot and dry weather early in the summer checking the growth before it became properly matured. The showers since causing an abnormal growth to be made resulting in premature flowering. In a general way the blossom now expanded is upon the points of the shoots. When these are of any length in pruning the tips are generally cut off, so that flowering now will not injure the trees. Nipping off the blossom at once is all that can be done just now.—S. P.

This is a result of the extraordinary season. It will not, of course, do the trees any good, and the best plan, if the flowers are numerous, will be to cut them all off. Even if they set, however, the fruit would come to nothing now.—B. C. R.

This is doubtless due to the remarkable character of the past season, and unless the trees are in full bloom, which we presume is scarcely the case, will do no harm. The flowers will not get fertilized, and, therefore, not bear fruit, of course. It is best to leave the trees alone.—C. T.

HOUSE & WINDOW GARDENING.

CAMPANULAS FOR BASKETS.

CAMPANULAS FRAGILIS or Barbellieri, C. garganica, and C. isophylla alba (see illustration) are the best varieties for baskets, the two first named producing long sprays covered with large blooms of the softest hue, and the latter lovely white flowers in rich clusters and masses, if well grown. Plants which have now ceased blooming can be propagated either by cuttings or by division of the roots. Each bit, with a root attached, can be placed in a 3-inch or 4-inch pot, with a compost of leaf-mould, loam, and sand, for the winter, taking care to supply good drainage, covered with Moss dipped in soot, to keep insects out. An occasional watering will be all that is needed for these plants until March, and while on this subject it may be desirable to explain exactly what is meant by an "occasional watering." Many amateurs injure their plants in winter by a system of giving water in dribbles—i. e., they supply a few teaspoonfuls to the top of the pot whenever the soil appears to be dry. This results in the gradual dwindling and death of the principal roots, which never get any water at all, being at the bottom of the pot and the plant looks

all vigour, if it does not die. The proper way to give water is to supply enough to run through the pot at one time, but if saucers are used these should be emptied about an hour after the water is given, which should be in the morning during the winter-time. Having been thoroughly soaked they will not need more for some days, and the test of dry soil on the surface may then be safely applied. To return to the culture of Campanulas. They will need a shift into their flowering-pots early in March, and the soil then used may contain a little old hot-bed stuff, as well as leaf-mould, and a pinch

Campanula isophylla alba.

or two of soot, with enough sand to lighten the compost. Placed in a sunny window, and more water supplied as needed, the Campanulas will soon throw down their flowering sprays, making charming objects either in a basket, a window-box, or balcony. Blue and white flowers are so beautiful that they should be grown by everyone, for they give a delightful variety to the mass of reds and pinks which abound in summer.

4580.—**A Fern-case.**—To grow Maiden-hair, Pterises, &c. in a large Fern-case air is indispensable. It is only a few of the small Filmy Ferns and Lycopodiums that seem to be able to do without such air. Stagnant water, too, will not suit them, and there should certainly be holes for drainage, or a false bottom of perforated zinc, through which the water may pass into a tray which can be emptied. The best way to give air would be to have one of the upper panes made movable, so that fresh air can be given daily without draughts, and the damp which accumulates on the glass roof should pass away without dropping again on the Ferns, for this causes them to mildew and soon decay. The soil too is not suitable for the Ferns named. Plenty of good yellow loam should be mixed with the peat, and also silver sand and charcoal. Bits of crocks, chopped Moss, and old mortar-rubbish will also help to keep the compost light and sweet. When so much shut out from the air this is not always an easy matter. Thorough drainage should be given, and this covered with Moss, sprinkled with soot, to check the inroads of insects, and it is well to examine the soil carefully for these (after allowing it to become very dry) before it is used. A suitable Fern for a large Fern-case is Lygodium scandens (the Climbing Fern). It has very beautiful light fronds, and is most interesting in its growth. Pteris tricolor is also a very beautiful Fern with distinct mid-ribs of bright-pink. Adiantum fragrantissima has exquisite lacey fronds, with a sweet scent, and should certainly be included in the collection, with Pteris cretica and P. serrulata cristata, also very distinct, and Lomaria gigtha, a very handsome plant, in shape like a small Tree-Fern. One or two richly tinted fibrous Begonias will add much to the beauty of the Fern-case, notably B. "Louise Clouson," a very dark-crimson leaf, and B. Arthur Malet, a handsome, brightly coloured variety of Begonia

Rex. Tradescantia zebrina and T. multicolor will also grow well in a fernery, when thoroughly supplied with drainage and air, as well as with soft-water, which should be given lukewarm in winter.—I. L. R.

4573.—**Azalea in a window.**—By the time these lines are in print the Azaleas should certainly be taken inside the window—i. e., before sharp frost sets in. These plants are by no means easy to manage well in a house, for they need damp, cool air, and will not stand dry fire-heat, which induces their special pest, thrip, to flourish and destroy the foliage. The best place for them in a house during winter is the window of a bathroom, where the hot-water pipes keep the atmosphere from going too low, and a little steam from hot water can be let on two or three times a day to moisten the air. Failing this, they may be wintered in a bedroom without a fire, standing on a large tray or a flat bath, which should be kept with an inch or two of water in it, the plants standing on inverted saucers, not in the water, the use of which is to moisten the air for them. If they have any thrip on them (which may be ascertained by examining one of the older leaves) they should be dipped in a bucket of soft-soap and Quassia-water (made with 2 gallons of boiling water to a tumblerful of Quassia-chips and 2 oz. of soft-soap) several days following, after which a good washing with pure water once a week should keep them clean, and they may be put outside in mild, gentle rain with advantage to cleanse their foliage. Azaleas must never be allowed to want for water, but neither must they be soaked when they do not need it, a plentiful supply of lukewarm water being given to them whenever the surface soil is fairly dry. After flowering, every blossom should be picked off as it fades, and the plants repotted, giving them all the moist warmth available while they are making quick growth at this time, with abundance of water. After the end of June the plants are better out of doors; but thrip must be guarded against, and destroyed by dipping or sponging all the year round.—I. L. R.

Azaleas are not very good window plants, the reason being that they do not get enough light and air; the only chance of a measure of success is to keep the plant outside as much as possible. Azaleas are not injured at all by a few degrees of frost—indeed, they are benefited thereby—as red-spider and thrips cannot live in frosty weather. Of course it would not do to allow the roots to be frozen; and in winter, when the frost is severe, the plant should be taken indoors. My plants are all outside now, and they will not be taken in until October.—J. D. E.

INDOOR PLANTS.

4594 and 4602.—**Aspidetras.**—The most suitable compost for these plants is a mixture of sandy loam and leaf-mould, three or four parts of the former to one of the latter. Drain well, and pot moderately firm. Water should be given only when the soil becomes moderately dry, and a little very weak manure or soot-water occasionally only during the season of active growth. If too much water or nourishment in any form is given the foliage of the variegated forms is apt to revert to the green-leaved type.—B. C. R.

"Enquirer" will find it impossible to prevent the variegated form of the useful Palm from reverting to its normal type. No treatment, except one calculated to keep the plant in a low state, will secure this result. Variegated sports all revert to the type more or less, more particularly when the subject is doing well.—F. U.

4609.—**Treatment of an Orange-trnee.**—All that can be done is to keep the plant as cool as possible during the winter and spring, when it will probably flower in a greenhouse temperature about the required time. Everything flowered much earlier than usual this year, owing to the forcing sunshine. Again, a plant that has been forced in any way one season always flowers earlier naturally the next.—B. C. R.

4617.—**Treatment of Camellias.**—Probably the plants have been insufficiently watered during this exceptionally dry summer, and drought is of all things injurious to the Camellia. Or perhaps they have been too freely exposed to the scorching sun. At any rate, the young leaves fading denotes that there is something wrong at the root. It would be best to turn

the plants out of the pots and examine the roots; if necessary repot them in smaller sizes, cutting away all dead or diseased roots, and using some fresh and very sandy peat round them, with good drainage. If possible give them a very gentle bottom-heat afterwards, but keep the tops cool and airy, and give water with the greatest care.—B. C. R.

—The small leaves turning colour seems to show that the growth of this last season was not equal to that of preceding years, and the probabilities are there is something wrong at the roots. Perhaps drainage is wrong, and the soil sour and pasty. Better examine and put right as soon before winter sets in, or matters will get worse.—E. H.

4610.—Plants for a conservatory.—You could not have sent your inquiry at a more unsuitable time of year than the present, because there is very little that can be done for the next four months in the direction you require. It is much too late to sow seeds of *Primula* and *Cineraria* to produce plants for winter flowering; you may, however, sow *Cycolamen persicum* and grow the plants on for next year, and if fire-heat be only used to keep out frost you may sow at once such subjects as *Mignonette*, *Primula obconica* and *floribunda*. After Christmas you may sow seeds of the Green-leaved Zonal and Show *Pelargonium*, *Coleus*, *Balsam*, *Torenia*, *Abutilon*, *Alonsoa*, *Rhodantho Manglei*, Double and Single *Petunias*, *Browallia elata*, *Lantana*, *Heliotropis*, *Streptocarpus* in variety, and *Trachelium coerulenum*. Most of these subjects will strike from cuttings during the summer when you have obtained a stock of plants.—J. C. C.

4604.—Margarites for winter.—The plants must be kept near the glass in a light, sunny window, but remove them further into the room on frosty nights. Water them only so as to keep the soil just moist, and the foliage fresh, and give a little very weak soot-water occasionally. Unless good, strong plants, and the pots full of roots, they will not bloom much during the dark days in a room.—B. C. R.

4598.—Greenhouse during frost.—Strictly speaking, you should not endeavour to grow any subjects under glass without possessing enough fire-heat to protect them according to their requirements, independent of outside coverings. Darkness is not beneficial to the majority of plants. In the case of sharp frosts the best and easiest covering is probably a few good St. Petersburg mats, and these may sometimes be used to advantage during extra sharp nights or a spell of severe weather.—P. U.

—There is nothing to surpass, if to equal, for this purpose the material made specially for it, and called "Frig-dome." If expense is an object, old sacks of stout material sewn together will be found very useful.—B. C. R.

4637.—Heating a small greenhouse.—You are only experiencing the same trouble as many other young people who have to deal with these small boilers, and I really do not know how to advise you. Certainly the placing of a steam-pipe near the cistern and carrying it outside will not help you much, as it will tempt you to ignore the possibility of all the water being discharged from the pipes and boiler out of this pipe, and then a burst boiler will be the result. You had better clean out the flue-pipe once a week, and in windy weather keep the wind from reaching the fire as much as you can. You must follow the directions with regard to keeping the supply cistern filled above the entrance to the top pipe, or the water cannot circulate. You had better use a coke-crusher for breaking the coals, as you cannot improve on the fuel you use.—J. C. C.

4620.—Building a glass house.—Yes; it will certainly be advisable to have some ventilators fixed in the ridge, two or three at least on each side, top air being not only necessary for Tomatoes and *Chrysanthemums* (and generally far preferable to a through draught), but absolutely necessary when forcing *Rhubarb*. A good method of arranging the roof ventilators in houses that, like this, are constructed of lights or sashes, is to support the edge of the latter on stout rafters out about 8 inches longer than them, so as to leave a space of that width between the top of each sash and the ridge-plank. These apertures will act as ventilators, and are to be closed, when necessary, by lengths of 9-inch board (the same length as the width of the sashes), hinged to the ridge-plank. Of course, glazed ventilators would be better; but the above arrangement answers all purposes, and is very inexpensive.—B. C. R.

—I have read down your enquiry several times, still I am perplexed to know what sort of

sashes you have, seeing that you have only six in number, and the proposed length of house 36 feet. Then you speak of ventilators under the eaves, and the height of span 6½ feet and 10 feet wide. If these figures are correct, do you not think the roof will be very flat? I point this out to you because your information is not very clear. For Tomatoes you will require ventilators in the roof, and the simplest way of providing them in your case is to adopt the Paxtonian system of ventilating, which has narrow lights about 10 inches wide, running up from eaves to the apex between each two sashes. For your purpose I should say 1½-inch hoards, 8 inches wide, would do as well as glass-lights for opening.—J. C. C.

MONSTERA DELICIOSA.

A NOBLE plant than *Monstera deliciosa*, or *Torenia fragrans*, as some call it, we could not name, either for the stove, greenhouse, or the sub-tropical garden in summer. Apart from its stately aspect, it bears large succulent fruits possessing a luscious Pine-apple flavour. In some gardens it is, like the Banana, grown specially for its fruits, and is considered a choice addition to the dessert. Though the gigantic stature of this noble Aroid, such as it assumes in its native habitat (the forests of Mexico), can only be seen in spacious hot-houses, as for example in those at Kew, which are devoted exclusively to tropical Aroids, still it may be grown to perfection in small houses provided there are sufficient heat and moisture. It is never, however, seen to advantage unless it is so placed that the roots have free access to water in a similar manner to that suggested by the annexed engraving, which represents a fully developed specimen bearing fruits. It delights

fruits it certainly presents a highly ornamental appearance. A high temperature and dense shade are, however, by no means necessary for its welfare; it enjoys a light, somewhat airy position, and when so placed it assumes a more shrubby, compact, short-joined habit. It should always find a place in sub-tropical arrangements, as it does well in sheltered nooks or similar situations throughout the summer. Although the *Monsters* will thrive in a low temperature, it will not develop its true character as a fruit-bearing plant unless a brisk growing heat be maintained during the spring and early summer months. The elements of success in order to obtain fruit are heat, light, and moisture, and, providing these conditions be one and all supplied, success will be ensured. Any form of training may be adopted which will bring the plant well up towards the glass. It may be made to cover a portion of the whole of the back wall trellis, or, what is preferable, it may be trained round forked trep-stumps, a system which suits it admirably. It may be grown in a tub, but preference should be given to planting it out in a good body of fibrous peat and loam in equal proportions, and which should rest upon a good drainage of brick rubble. Thus placed, unlimited supplies of water may be given in hot weather, and the fruit will be fine in quality and abundant. The engraving represents the *Monstera* growing against a house at Funchal, Madeira. G.

CHRYSANTHEMUMS.

SEASONABLE NOTES.

No time should be lost in placing under cover any plants that exhibit the slightest sign of colour in their forets, or any plants that are late in the formation of their flower buds. In the former case it is useless to allow them to remain out-of-doors longer in the hope of retarding the development of the flower-buds. What with rain and heavy night dews the flower-buds are rendered soft, and when the forets unfold they are almost certain to damp, which is disappointing after so many months' toil and attention. It is better to house the plants at once and reap the benefit of the flowers, even if they are a bit too early for exhibition purposes. In the case of the late budded plants they are so much more likely to suffer from an early frost than those plants which have their buds more forward, but not yet bursting of their forets. The growth, being immature at the point, is more susceptible to frost, therefore it is wisest to place these under cover, even if it were only for the sake of preserving them from harm in that direction. The buds will, however, swell so much faster if placed in the greenhouse than though they remained out-of-doors. Any foliage infected with mildew should be cleansed before the plants are taken inside by the usual remedy of lime and sulphur hoiled together, and syringed over the affected parts. A full description of the method of mixing has several times been given in GARDENING. After the plants are hoiled they should receive abundance of air, both night and day, and be arranged as near to the glass as possible, or the growth will be weakened at the points, which is not consistent with their requirements. I prefer to see plants with stout peduncles, these being sure indications of good blooms to follow. In plants that are late in their bud formation

OUR READERS' ILLUSTRATIONS: *Monstera deliciosa* at Funchal, Madeira. From a photograph sent by Mrs. A. H. Bridson, Rockville, Dartmouth.

In places where it can cling to a moist wall, or twine its plant branches round the stem of a tree for support, and where also its thong-like roots can dip and ramify in a water tank, which is usually placed in all houses devoted to tropical plants.

When grown in these hot, moist stoves it develops rapidly, and its singular perforated foliage, together with the quaint forms which it often assumes, strikes the uninitiated with wonder, and when studded with its clusters of

fruits it certainly presents a highly ornamental appearance. A high temperature and dense shade are, however, by no means necessary for its welfare; it enjoys a light, somewhat airy position, and when so placed it assumes a more shrubby, compact, short-joined habit. It should always find a place in sub-tropical arrangements, as it does well in sheltered nooks or similar situations throughout the summer. Although the *Monsters* will thrive in a low temperature, it will not develop its true character as a fruit-bearing plant unless a brisk growing heat be maintained during the spring and early summer months. The elements of success in order to obtain fruit are heat, light, and moisture, and, providing these conditions be one and all supplied, success will be ensured. Any form of training may be adopted which will bring the plant well up towards the glass. It may be made to cover a portion of the whole of the back wall trellis, or, what is preferable, it may be trained round forked trep-stumps, a system which suits it admirably. It may be grown in a tub, but preference should be given to planting it out in a good body of fibrous peat and loam in equal proportions, and which should rest upon a good drainage of brick rubble. Thus placed, unlimited supplies of water may be given in hot weather, and the fruit will be fine in quality and abundant. abound be pushed on by the aid of sulphate of ammonia. This is a powerful stimulant, but on excellent one as well if used carefully. Half an ounce in one gallon of weak liquid-manure will assist the plants perceptibly if given twice every week. If any roots have become bare on the surface of the pots owing to repeated waterings, it is advisable to apply a thin top-dressing of turfy loam and bone-meal, two parts of the former to one of the latter. Not only will this assist the development of the blooms, but it will render aid to the sucker-like growths from the base, and which form the cuttings for the next year's supply of plants. Now is the time to feed the plants regularly, and with a change of food occasionally. While the florets are expending, the plants need all the aid possible; the greatest strain is at that time felt, and if artificial assistance is not available the results cannot be quite so satisfactory as otherwise.

BUSH PLANTS are looking remarkably well this season, the earliest batch are swelling their flower-buds freely. The later lot, such as Leon Franche and M. E. A. Carricre, have not set their buds as yet. I do not pursue the disbanding practice with bush plants, but prefer to allow them to develop all available blossoms. They are so useful for cutting when in a mass on long shoots for filling vases that to limit the bush-plants to the development of but a few blooms each seems to be a waste of time and means. Those plants that have set all of their buds—for instance, Lady Selborne and the Rundle family—should be finally staked. One stout stake to each main branch is quite sufficient, loosely tying the side growths to this one main branch. Not only do so many stakes in each pot have an unsightly look, but they injure the roots when small pots are employed. The pots will now be crammed full of roots and should never be allowed to become dry, or the foliage will suffer in consequence, which spoils the appearance of the plants as decorative objects. Plants growing against walls are looking remarkably well where the roots have been well supplied with water, the hot sun just having suited them. The final nailing of the main stems to the wall ought to be done without delay. Where side growths are numerous they should be secured to the main branches by raffia, which gives a less rigid appearance than fastening all the growths to the wall itself.

E. M.

4608.—*Chrysanthemums from seed.*

In the first place, the plants must have been at any rate partially starved, and exposed as much as possible, so as to obtain the open or yellow-eyed flowers, from which seed is most easily and successfully obtained. High feeding develops the petals (which are sexless and barren) at the expense of the sexual or seed-producing organs. The pollen (a yellow dust) must be taken from a flower in which the stamens have just begun to liberate it, and applied (either by means of a small soft camel-hair brush, or by gathering the one flower and applying it directly to the other) to another from which the pollen has all, or nearly all, been shed, this being done in a warm dry atmosphere, with, if possible, the sun shining at the time. Afterwards keep the head warm, dry, and free from insects; the best place is near a hot-water pipe, where the constant current of warm air will effectually prevent damping. Gather the seed when ripe, and store in a dry place till the spring. Raising the plants is a comparatively simple matter. Sow the seed in the end of February, or beginning of March, in a gentle heat, pricking them off when large enough, then potting them singly, and finally shifting into 8-inch or 9-inch pots in June, and standing them out-of-doors. All will flower the succeeding autumn, but remember that a seemingly poor flower the first year will often improve vastly the second one, while in some cases the reverse will obtain.—B. C. R.

Chrysanthemum M. Gustavs Grunerwald.—This *Chrysanthemum* has proved to be very early, for even here in the North of Scotland I had it in bloom in the middle of June. It may best be described as a Pink Mme. Desgrange. It possesses a great advantage in the fact that every flower-stalk rises a good distance from the foliage, and thus all the blooms can be cut with profit. In Mme. Desgrange the ends are crowded together, and blossom close to the

foliage. M. Grunerwald is dwarf and very floriferous. Amateurs should make a note of this variety as a pot or bedding plant as a companion to Mme. Desgrange and its varieties.—J. G. W.

OUTDOOR PLANTS.

4624.—**Blue Gum and variegated Agavus.**—Unless the winter is exceptionally severe, both subjects will probably be quite safe in a sheltered garden near the south-west coast. Last winter we unseasonably trying, a severe and prolonged frost exceeding a very mild and moist autumn, which, of course, rendered the growth of everything soft, and unable to withstand the cold. Should severe weather seem imminent plenty of dry ashes should be heaped up round the plants before it sets in, and then the former, at any rate, will spring up again from the root, even if the tops are cut off.—B. C. R.

Both the Blue Gum and the American Aloe would probably live out in a sheltered garden on the south-west coast in an ordinary season. I remember seeing a Blue Gum which had grown to a large size in a garden not far from Exmouth some years ago; but I do not think the variety was *globulus*. However, *globulus* is probably as hardy as any, and I remember about the same year, 1878, I think it was, seeing a large plant of *globulus* in a garden on the banks of the Mersey, near Liverpool. In ordinary seasons these plants will doubtless survive in sheltered gardens; but occasionally we get an extraordinary frost, and away goes the plant we have nursed and cherished. However, it is better to have loved and lost than not to have loved at all.—E. H.

4597.—**Daffodils for a small border.**—The following are cheap, and will flower well: *Bicolor nobilis*, Trumpet-major, *chavallis* (the Tenby Daffodil), *Pseudo-Narciss* (Single Lent Lily), *Telemachus plenus* (Double Trumpet Daffodil), *incomparabilis flore pleno* (Butter-and-Eggs), *Grange Phoenix* (Eggs-and-Bacon), *Leeds posthous*, (*Phœasant's-eye*), *ornatus*, *Donnie Roman*, and *Scilly White*. The sooner Daffodils are planted the better.—E. H.

4596.—**Planting a Pentstemon.**—This should be planted out early in May. If you have the plant already, I should recommend you to pull off the side shoots as soon as they are about 4 inches in length (they will come away with a little toothed heel), and pluck off the bottom two pairs of leaves; prick them into a bed of light soil, and cover with a hand-glass. By bedding time next year, each of these will have made a strong plant. The *Pentstemon* is more than half hardy, and will survive a mild or dry winter without protection, but a wet winter with severe frosts kills those, as it does many other reputed hardy perennials. *Ceanothus* is a creeper sometimes called hardy, but severe frosts frequently kill it.—A. G. BUTLER.

I should advise you to keep *Pentstemons* over the winter in a frame. They are very beautiful flowers, but get much hurt in severe winters. I have a bed of them, and trusted them in the open, but the majority got killed by the frost. A cold frame or a greenhouse will suffice, delaying planting out until the spring. *Pentstemons* will live in ordinary garden soil, such as is suitable for *Pelargoniums*, and have this year proved, in spite of the severe drought, amongst the finest flowers of the year. They are still gay with flowers, and in late August or early September were a picture of colour. There are many varieties, the names of which may be ascertained by referring to good catalogues, and the more delicate shades are remarkably pleasing.—C. T.

The spring is the proper time to plant out this and all other subjects of doubtful hardiness. Towards the end of April (the weather being fine and mild) or at any time during May is the best period.—B. C. R.

I would advise "Florence" to wait until March, or early in April, before planting out any of these flowers. Although they are quite hardy in some localities, in others they are only half-hardy, and she would do well to avoid any risk during the coming winter. Any cold frame or pit will afford all the protection needed by a *Pentstemon*.—P. U.

4628.—**A town garden.**—According to my experience, Carnations will keep better right away from a wall or any other protection than they will close to it. Probably you have no choice in the matter. In that case do not be tempted to coddle your plants in any way.

Press the soil firmly about the roots now, and two or three times during the winter after frost, and when the surface is dry, and leave them to their fate. If you have very choice varieties you had better keep them in a cold frame until the middle of March.—J. C. C.

I am pleased to hear you have started growing Carnations; they are excellent town plants, as one may judge from the many fine specimens to be seen near London. One of the best amateur growers lives at Clapham. I had some good Carnations this summer, and did not protect the plants in any way, merely making the soil about them firm when weather permitted. Frost sometimes almost throws them out of the ground. Another amateur, residing near, did exceedingly well with his Carnations, and, I believe, did not protect in the slightest. Give a top-dressing of wood-ashes or well-rotted manure in the spring, and in the event of very severe weather a little Bracken placed amongst them will do no harm. One great point in their culture is to plant the layers in September, so that they have a good season to get established in before severe frosts appear and put a stop practically to growth. As you ask for a few hints, I may say that the soil should be of a good loamy character, plant firmly, and in spring go over the stock, press them well into the soil, and throughout the summer give water whenever the ground gets very dry. In the spring the top-dressing may be given, and little attention is required until it is time to layer in the month of July. Get in your selection a fair proportion of selfs. I have recently given a small list.—C. T.

Carnations are perfectly hardy, and need no protection during winter. The only thing which causes them to die in the cold weather is excess of damp. Last winter many rotted from the unusual abundance of wet weather. Cotton-wool-fibre would tend to retain moisture at the collar, and would, in my opinion, be decidedly injurious.—A. G. BUTLER.

I should strongly advise you not to touch the Carnations in any way. As far as I am aware, the soil of Clapham is light and well drained, and this being so, strong plants of hardy varieties planted in good time will be perfectly safe. If kept fairly dry the Carnation is a perfectly hardy plant. A little ashes would be the least objectionable; but even this is unnecessary.—B. C. R.

4575.—**Laying out a small plot.**—This is too narrow a slip of garden to do very much with, yet with good management it may be made to yield its possessor a good many flowers. Possibly the area for growth may be increased by one or more arches, such as are now so well supplied ready-made in wire for such purposes, and these, as well as the south wall, may be covered with such creepers as a *Gloire de Dijon* Rose, *Clomatis montana*, and *Clomatis Jackmani*, *White Jasmine*, *Yellow Jasmine* (*J. nudiflorum*), *French Honey-suckle* (*Lonicera sempervirens*), and *Virginian Creeper*. The first thing to be done is to dig the plot thoroughly to the depth of 18 inches, working in some stable-manure (a barrowful) and plenty of soot from the chimneys, if possible, or if the soil is very poor, taking it out and putting in a few barrowfuls of good turf-mould from an old pasture. The creepers can be planted in October, and the soil should be renewed at once to be ready for them, for careful planting is necessary to success. When they are turned out of their pots the roots should be spread out in a fan-shape, about 6 inches below the surface, and then covered with fine soil and trodden in till the plant is quite firm in the ground, the long shoots being nailed at once to the wall or tied to the wire arches. In front of the creepers a bright bed of bulbs may be planted *Crocuses*, *Scilla sibirica* (sky-blue in tint), *Tulips*, *Hya-cinthus*, and *Narcissus*, all of which will make a gay show in spring, or stout little plants of dark-red *Wallflowers*, *Forget-me-nots* (*Myosotis disitiflora*), and *Pink Donnie Daisies* will look equally well in spring. Any summer bedding plants will succeed well here if thoroughly supplied with water; but in arranging them it is well to break up the stiff line into groups, in the middle of each being a handsome tall plant, with others graduated in height around it, the lowest being kept in the front. Stiff lines are always ungraceful, but much may be done to avoid them by this plan, trailers being used in front to break up the edging line as much as possible. Definite lists of plants for this border in summer can be given, if desired, in the spring. *Lilies* and *Gladiolus-hilms* may be planted in October and March, and will be very suitable for this border.—I. L. R.

ORCHIDS.

ONCIDIUM LEUCOCHILUM.

This is a very beautiful and showy plant, one that is well distinguished by its pure white lip, which is so very different to the majority of the Oncidiums. I have now before me a nice little spray of fine flowers, which are each nearly 2 inches across, and have the sepals and petals spreading, nearly equal, with a ground colour of yellowish-green, barred and blotched with very dark blackish-brown. The lip is large and pure white. The sender, "Thos. Hudson," asks if it is a plant which requires much warmth, because he fancies that all white-flowered Orchids are tender, and having this plant presented to him, he would like to grow it well. This Oncidium was first introduced into our gardens from Guatemala, now nearly sixty years ago, and in those days it took much longer to traverse the distance from that country to this than it does now, when we have such ocean greyhounds as we have in our fast steam vessels; but, however, even in those days the plants reached this country in a living state, and soon afterwards flowered. The plant was collected in Mexico as well as Guatemala, and was imported by various people, and it became very popular when I was young amongst Orchids, and about that time it was frequently to be seen at our great London exhibitions; but in the present days one seldom sees it grown; in fact, the present race of gardeners and amateur Orchid growers would appear not to know the plant, and this is the more to be wondered at when it may be grown in the cool-house with the now popular family of Odontoglossums and other things. And certainly the very finest plant and most superb variety I ever saw was once when visiting the unique collection of the late Mr. Dawson, at Uddingstone, near Glasgow. This plant stood out in a cold-house, and it was in the most robust and vigorous health and blooming profusely, the individual flowers being large in size, the lip pure white, the other segments being nearly black. Now, this plant, which I hope will regain its popularity, is a remarkably good and free grower, requiring but to be potted in good peat-fibre and Sphagnum Moss, and to be well drained. In potting the bulbs should be set up above the soil in a little mound. It should receive a good supply of water during the growing season, and the atmosphere should be kept in a nice moist condition. Much less will suffice during the dull season; but I have always found it throw up its spikes freer if not dried in the winter, but it should be kept cool.

MATT. BRANBLE.

THE KITCHEN GARDEN.

RHUBARB AND ITS CULTURE.

This will grow in many kinds of soil; but the richer and deeper it is the finer will be the quality and size. The situation should also be moderately dry, or made so by drainage. It will grow in clay, peat, or bog-earth of the Fens. I have seen it succeed remarkably well in mud cleaned out from the river. When the leaves get fairly into growth they need plenty of food to keep them growing. The larger the leaves of one season the stronger will be the crown for the next; hence the importance of rich feeding all through the growing season. It is a good plan in small gardens to plant Rhubarb near the depot for house sewage, so that it may be nourished with this as well as solid manure; 4 feet, at least, of rich root-run should be provided for it. For new plantations the ground should be thoroughly trampled and manured. Its productive force should be kept up afterwards by an annual dressing, from 2 inches to 3 inches in thickness. No plant is more easily increased and multiplied than Rhubarb; plants two or more years old seed freely if permitted to do so. Unless seed be required, however, they should not be allowed to do so, as seed-bearing weakens the crowns. The seeds ripen about the end of September, and may be sown at once in shallow drills a yard apart, or they may be sown in February. As soon as they are well up thin the plants to 18 inches or 2 feet asunder, according to the size of the kind and the intention of the cultivator. If intended to remain where they are, a yard apart is large enough;—in fact,

too close for some varieties. Some, however, prefer rows 2 feet apart, and thinning the plants to 1 foot only the first season; then in the October or February following fresh ground is prepared, and the Victoria kind is transplanted at distances of from 4 feet to 6 feet by 4 feet, and the Debaunce 3 feet by 18 inches or 2 feet. The best plan is to sow Rhubarb where it is to remain, as it forms immense roots that are easily broken—and to break it is to injure it more or less. Nevertheless, a very common mode of

PROPAGATING RHUBARB is by root division. The huge stool or fleshy root is sliced into as many portions as there are crowns to it with a sharp knife or spade, and each slice forms a new plant. Gathering Rhubarb, and when to cease gathering, are matters which require more attention than they generally receive. In gathering, the proper method is to give the leaf-stalk a twist outward, and a sudden jerk down at the same moment. From want of attention to this, many tear off the crown with the base of the leaf-stalk. Again, too many leaves should not be gathered at once. If a plant have only a dozen leaves, do not gather more than six of them, and let these be the lowest. Some prefer Rhubarb when the leaves are freshly unrolled, others when they are half-grown, and others when they are fully grown. Of course, there is great waste if the stalks be gathered before they have reached their full length. Rhubarb is at its best just when the leaf has reached full size. It can hardly be too old for preserving, and is seldom gathered till the end of August for

A bundle of well-grown Rhubarb.

that purpose. As to the time of ceasing to gather Rhubarb, it should certainly be not later than August if the gathering is to be annual; this leaves but little time for the last leaves to ripen good crowns for the next year's crop. All the leaves removed have doubtless been a loss to the plant—they did much to weaken and nothing to strengthen it; it is only the leaves left on that recoup it for its loss in those taken off. Hence the importance of rich food to replenish the plant, and time for the maturation of the later growth; and it need hardly be said that no wood must be permitted to grow at the expense of the Rhubarb plants.

FORCING RHUBARB.—There are various ways of forcing this useful plant, which may briefly be divided into two distinct methods: No. 1, consisting of lifting the roots and placing them in artificially-heated structures; or No. 2, by covering the crowns where they are grown with pots or boxes, and applying forcing material, composed of stable-litter, leaves, &c. or, in fact, anything that will generate warmth enough to excite growth. There is much to be said in favour of both systems, for they are both good under certain conditions, and gardeners in private gardens, as a rule, find lifting the roots and placing them in heat the best plan for the earliest crops during December and January; for where heated glass structures are in use, a supply of Rhubarb may be procured without any additional outlay, or even occupying any space useful for any other purpose, as under stages, or in the boiler-shed, or, in fact, any position near the hot pipes. The roots may be placed on the floor, or in pots or boxes, and

covered with soil, keeping it moist, and the crowns may be covered with hay, Fern-fronds, or litter to blanch it. The only objection to this plan is that it weakens the crowns more than by forcing them in the ground, as the roots get very much mutilated in removal, so that if the quantity of Rhubarb roots is limited, it is preferable to adopt the plan of forcing the roots where they are grown. Procure the requisite number of pots, with movable covers, and place them over the crowns; then cover them over with fresh stable litter or a coating of leaves and litter mixed together. The leaves of deciduous trees are most useful for many purposes, as they can be used for forwarding crops of Rhubarb and then placed in pits or frames for supplying bottom-heat for Cucumbers and other early crops. To have Rhubarb fit for use at Christmas cover the crowns in the middle of November, and as soon as the first betch gets fairly started into growth cover a few more pots in succession until it comes on naturally in March, when any large tubs or boxes turned over the crowns to shelter from cold winds will forward the growth at least a fortnight before the crowns left uncovered. Rhubarb, unlike many other crops, is better when forced than from the open air, being more tender and succulent. In addition to the two well-known kinds first mentioned in this article other desirable ones are as follows: Mitchell's Royal Albert or Early Red, an excellent and very early sort; Scott's Monarch, a giant variety of much excellence; Hawke's Champagne, the favourite London Market sort; and Myett's Linneus, a second early kind, of excellent quality. U.

4021.—Asparagus-bed.—Seed-bearing has an exhausting effect, and this is one reason why I advised its removal. Then, again, those who leave the seeds on the plants generally leave them to ripen and fall about the bed, where they grow and crowd the original plants to death; but this does not appear to be the case with "J. N. S.," as his bed is thin in place, and he might with advantage sow seeds or set out young plants in sufficient numbers to fill up the bed. The seeds may either be sown now or in spring. The seeds will grow earlier if sown now.—E. H.

4018.—White Tomato-fly.—Yes, if this attacks the *Chrysanthemum*, as it probably would, it would injure them considerably. I suppose for "stove" should be read "smoke," and if so, certainly, as two or three good fumigations would probably banish them entirely. Another excellent remedy for this pest is to syringe the affected plants with a solution of Calvert's soft-soap.—B. C. H.

RULES FOR CORRESPONDENTS.

Questions.—Queries and answers are inserted in GARDENING free of charge if correspondents follow the rules here laid down for their guidance. All communications for insertion should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF GARDENING, 37 Southampton Street, Covent-garden, London. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Unanswered queries should be repeated. Correspondents should bear in mind that, as GARDENING has to be sent to press some time in advance of date, they cannot always be replied to in the terms immediately following the receipt of their communication.

Answers (which, with the exception of such as cannot well be classified, will be found in their different departments) should always bear the number and title placed against the query replied to, and our readers will greatly oblige us by advising, as far as their knowledge and observations permit, the correspondents who seek assistance. Conditions, soils, and means vary so infinitely that several answers to the same question may often be very useful, and those who reply would do well to mention the localities in which their experience is gained. Correspondents who refer to articles inserted in GARDENING should mention the number in which they appeared.

4041.—Lemon-scented Verbena.—I shall be glad to know how to strike cuttings of this plant? I have tried two or three times and failed. Cannot get them to root.—I. B.

4042.—Flowers for Christmas church decoration.—What flowers could I get now to have them in bloom for Christmas church decoration? White preferred.—OXFORD.

4043.—Colours of Violets.—Will anyone very kindly tell me what colours are the following sorts of Violets? Maille Louise, Comte de Brazza, Mme. Millet, and De Parme.—JURONAMUS.

4044.—Freesias.—Will someone kindly say if it is right for Freesias to be very long in the leaf and drooping? I planted them early last month in pots in a vinery, and they have grown about 8 inches long now, and are hanging down. Should they be left in the vinery or put in a cooler house?—A BEGINNER.

4646.—*Gloriosa superba*.—Will someone kindly tell me how to treat the above bulb the year through? I have just had a bulb sent me, and I do not know it at all. Is it valuable, and how should I manage it?—G. B. W.

4646.—*A frame-pit*.—Will someone kindly tell me the best way of making a frame-pit for keeping plants in the winter? What depth should it be? Is there any kind of heating apparatus for burning oil that could be used?—O. W.

4647.—*Oil-stove for a greenhouse*.—Will someone kindly recommend the best oil apparatus to heat a greenhouse, 12 feet by 6 feet by 6 feet high? About what it would cost to keep frost out?—AMATEUR, Hailham.

4648.—*Shrub-entails for a dry situation*.—Will anyone kindly advise me as to the best shrubs to plant in a garden where the soil is drawn and partially covered with a large *Besch-tire*? The soil is a sandy loam.—BROMLEY.

4649.—*Keeping Fuchsias through winter*.—I have a quantity of Fuchsias in pots. If I cut them down to the pots can I keep them through the winter laid on their sides in the cellar with *Delias* and *Begonias*? I am short of room.—H. B.

4650.—*Purchasing a greenhouse*.—I am about to purchase a greenhouse. Will someone advise me? Should I buy one as advertised, or should I have one made at home by a carpenter? Also what sort of heating apparatus is best?—AMATEUR.

4651.—*Fruit in a cellar*.—Is a cellar a bad place for keeping fruit? I had mine fitted up with spere, and it has a window for ventilation; but a great proportion of the fruit seems to get water. It is not damp. Perhaps it is caused by an insect?—LINDEN.

4652.—*Nrains Fothergill*.—Will any of your readers tell me how to flower *Nrains Fothergill*, also the kind of treatment they require after blooming, also what soil they do best in, and when they should be potted and what temperature they require?—R. P.

4653.—*A lean to greenhouse*.—I have a lean-to greenhouse I wish to heat with a gas stove of some kind. Will anyone advise me of a good one to obtain? Size of house 30 feet long, 10 feet wide, 9 feet high in front, 12 feet high at back; Southampton.—DAYTON.

4654.—*Specimen sarsgreen trees, &c.*—Will someone kindly give me the names of about six of the best and most effective errorerers for lawns—three or four of the glaucous kind? I do not mind expense for good ones. Also of three or four of the best *Mandis*?—LANSIS.

4655.—*Treatment of a Bermuda Lily*.—Will someone please to say how I am to manage *hermudis*? This here six blooms last year, but none this! The flower stalks were blind, and I reported it about the time twelve months, when it leaves seemed withered.—A. M. G.

4656.—*Spring bulbs*.—What is meant by "sinking pots of bulbs in a bed of ashes"? Does it mean others of the fine dust which remains when the coal is burnt? Would a dark cupboard, heated by hot-water pipes, be a suitable place to put pots of *Tulip* and *Narcissus* bulbs in when first they are planted?—L. M. N.

4657.—*Mistletoe*.—I am anxious to grow some *Mistletoe*, and should be glad of any hints as to its culture? Last year I looted a berry in the bark of an Apple-tree, and it appears to have taken; but is there no quicker way to grow it, as I believe it takes many years like this to grow to any size?—PAUL PAX.

4658.—*Roses in an unheated greenhouse*.—I have a greenhouse in which I grow *Tomatoes* in summer in the beds each side of the path. Would a *Mercadal Niel* or *Niphetos* planted at the end of path trained up the end of house and along ridge, with one stem, thrive in that position? Any information will oblige.—E. M.

4659.—*Arranging a shrubbery*.—Will someone please to tell me how to arrange a small shrubbery in front of my house and at the sides? I want a variety, and to know the names of what sorts will grow best together? What distance apart should they be planted? Soil gravelly, in Southampton, facing west.—DAYTON.

4660.—*Loosing foliage of Chrysanthemum*.—A good number of my *Chrysanthemum* have lost their foliage, this time obfely *Alvanches*. I have never allowed them to get quite dry, standing in a single row facing west; county, Lancashire. Would someone suggest the cause, so that I may guard against it another year?—G. B. W.

4661.—*Clearing a ditch*.—In my field there is a ditch on my side, and a hedge on the other side of it. (a) Have I a right to clear the ditch of bushes and brambles overhanging it? (b) Have I a right to take water from the ditch? (c) If my neighbour levels the hedge and overlooks me, have I any remedy, and, if so, what?—JONOTUS.

4662.—*Sawdust as manure*.—Will anyone advise me as to the best way of treating sawdust that has been used for bedding? It soaks up a large quantity of animal manure, but it does not decompose very readily. What would be good to mix with it? I suppose lime would destroy the manure, and so make it all useless? How would ask about it?—M.

4663.—*Making a tennis-lawn*.—I wish to make a proper tennis-lawn, 80 feet by 40 feet wide. Will someone tell me how to proceed? I want it to be all Grass, and should like to sow it now if not too late? What quantity of seed would it take, and does it require any sowing other than the soil? Any information will be acceptable. Soil gravelly, in Southampton.—DAYTON.

4664.—*Fast-growing Fir trees*.—As my house and avenue are in full view of the public road I am anxious to shut out the view by planting a row of fast-growing evergreen trees, and would be glad to know the names of the latest-growing variety of the Fir tribe? Also the height they should be at planting time, and the proper time to plant?—WICKLOW, Ireland.

4665.—*Carnation seed*.—I should be glad if someone would give me a little advice as to sowing *Carnation* seed? I have tried this but have only succeeded in sowing two pods, one of *Harrico* and one of *Mrs. Reynolds* type, and they seem to be quite two months ripening. Would it be advisable when the cold weather comes on to take the pods off the bush ripening?—SOUTH STAFFORDSHIRE.

4666.—*A boarded fence*.—I have about 160 feet of boarded fence, facing north and south, also a brick wall, 50 feet long and 8 feet high, facing west. Will someone tell me what fruit-trees would do best in the different positions, and how far apart they should be planted? I should like as large a variety as possible. A few names of good sorts will oblige. Gravelly soil, in Southampton.—DAYTON.

4667.—*Fruit-tree round a large tennis-lawn*.—I wish to plant an espallier or ordon of *Fruit-trees* round a large tennis-lawn. Will someone please advise me what trees are most suitable, and the names of the best sorts; also when to plant, how to plant, distance apart, and how to make the espallier or support for the trees? Space at disposal 220 feet, gravelly soil, in Southampton.—DAYTON.

4668.—*Rhinbar and Mushrooms in a shed*.—I have made a lean-to shed 9 feet 6 inches square, 6 feet from the eaves. I intend to have a shelf 1 yard off the floor and 1 yard wide all the way round. Will anyone kindly give me information with regard to forcing *Rhinbar* and growing *Mushrooms* hard about Christmas? I may add that there are no windows in the shed.—REGLAR PRESBER.

4669.—*American Blackberry*.—Two years ago I bought a *Wilson Jun.* (*American*) *Blackberry*; it has grown well, and this year has bloomed twice, once in the early summer and is in bloom now, but none of the blooms set for fruit. The blooms are very double, like small *Roses*, and very pretty; but I should be glad to know why there is no fruit? It is trained on high fences, facing south-east, and is growing in good soil.—A. K.

4670.—*Plants for next season's blooming*.—Is it possible to grow any or all of the following plants to bloom next season? If so, will someone kindly give me a few cultural instructions, stating when the seed should be sown? *Campanula pyramidalis* (*Cantabury Belle*), single and double, *C. calyculata*, *Polyanthus*, *Double Delais* (*Belle*), *Cowslip*, *Eranthis Primrose* (*Crothera hians*), *Foxglove*, and *Pentstemon*.—AMATEUR.

4671.—*Window plants*.—What is the best method of keeping the ordinary class of window plants, such as *Fuchsias*, *Geraniums*, *Spireas*, *Hydrangeas*, *Marguerites*, &c., during the winter? I should like them to be cut down? I have no great room, but I have a frame in the garden about 6 feet square, and plenty of space in empty rooms in the house. Would either of these places be suitable, and how often would the plants require water?—L. M. N.

4672.—*Roses in pots*.—Will someone tell me what to do with my *Tea Roses* in pots which I have just placed in the greenhouse? I propose pruning them in January, and want to know what watering and syringing should be given them till then? I suppose they will not require any heat till then, and that they may have plenty of air, except when it is freezing? As some are still in flower, I intend repotting them in order—as they go out of bloom.—SOUTH WALE.

4673.—*Plants for conservatory*.—I have a small conservatory, size about 14 feet 6 inches by 13 feet 6 inches. I am anxious to know what flowers will be suitable to cultivate in it? I have at one end a rockwork filled with *Fuchsias*, principally *Maiden-hair*. As climbers I have a *Tacsonia*, *Sophanotis*, *Pimbaro*, and *Oleandra*. The house is heated with hot-water pipes, and so it opens from a room, I wish to feel it as comfortable as possible. Any suggestions will be acceptable.—AMATEUR.

4674.—*Restoring a lawn*.—I wish to know the best method of restoring a large lawn which has suffered seriously from the scorching heat and drought of the late summer? It has a due south aspect and slopes towards the south. In places the ground is quite bare, and as though there had never been any Grass on it; the banks also are in a very bad way. After the rain in July the bare places were sown with Grass-seed, but the return of the heat seemed quickly to destroy the young growth.—MRS. C. WOODLORON.

4675.—*Heating a greenhouse*.—I have a small greenhouse 10 feet by 7 feet, with an average height of about 6 feet. It stands north-west, and has a high 9-inch wall at back, and a stable against north-west end. Will someone, who knows from experience, kindly tell me if an oil-stove with a 3-inch wick would be large enough to keep it at a keen frost? Or, if not, what size stove ought I to have? I do not want a stove for forcing purposes, but only to protect such plants as "*Geraniums*" and *Fuchsias* from frost. What kind of ventilator would be required?—J. H.

4676.—*Carnations in a smoky district*.—As I live in a very smoky district, and am very anxious to grow *Carnations* well, I should be glad if someone would give me a little advice. I am building a low house, with some frames I have to keep the plants in to the wicket, and I am making it so that for the summer I can take the sides out and leave the roof on, so as to keep the flowers clean when they are in bloom. I should like to know if the plants will be as healthy with this arrangement? I have provided plenty of ventilation. I should also like to know if *Roses* would be likely to do well under similar treatment?—SOUTH STAFFORDSHIRE.

4677.—*Heating a large greenhouse*.—I have a greenhouse measuring about 18 feet long, 10 feet broad, and 16 feet high, which I want to heat only sufficient to keep out frost so as to preserve such things as *Cleoceras*, *Arum lillie*, *Geranium* cuttings and the like during winter. Will I be able to do this with an oil-stove or heating apparatus burning oil, as I cannot afford to fix a regular boiler and pipes? I have been recommended *Rippling* and *Stoves*. I may mention our winter here are very mild compared with English winters; some years suffering very little from frost. The advice of "*B. C. R.*" will be much esteemed.—WICKLOW, Ireland.

4678.—*A small coolhouse*.—I have a small coolhouse (span-roof), 12 feet by 8 feet; ends face north and south. I should like to devote it to Vines, or half Vines and half *Tomatoes*. Would "*J. C. O.*," or any similar amateur's friend, advise as to what sort to get? I should like variety—that is, light and dark ones. Where could I get the Vines? What distance apart, or how many canes would it take to plant on one side? Plant inside or outside? I have plenty of space to make an outside border. Would it be advisable to put in a flue with sanitary pipes? I have a heated house, but cannot spare room for the flue. When is the best time to plant, and information, especially would greatly oblige?—MINE.

4679.—*Ivy-leaved Geranium*.—I want to grow a couple of *Ivy-leaved Geraniums* up the sides of a small porch about 10 feet high, so as to have it thickly covered with bright green leaves and plenty of flowers to make a good show, and am anxious to know the names of the two best varieties for my purpose. I think I have seen *Madama Crocus* favourably spoken of in *Gardens* for such a purpose. I will not be able to raise a flag of the porch and plant the roots in the ground, but intend to plant them in boxes which I have had made to fit each side of the porch, measuring 22 inches long, 15 inches deep (inside measurement). In such large boxes I suppose the roots will not be in the slightest curled as the *Geranium* is such a small-rooted plant?—WICKLOW, Ireland.

4680.—*Ornithogalum arabicum*.—Although I fear that many amateurs have had much experience with this bulb, I am writing a query on the subject of its cultivation with the hope of getting some information on a rather curious experience! In the spring of the present year I purchased a dozen fine bulbs from a shop in London. I looked up the culture in the back volumes of *GARDENING*, and the bulbs were duly potted and placed in an ordinary greenhouse from which frost was excluded. Two of the bulbs died, and only one sent up a few leaves; but finding them still sound, the pots were turned out-of-doors for the summer, and occasionally watered. At the time of writing these bulbs are strong, plump, and green. They are rooted, and have much increased in size, although there has been with the single exception no top growth. Some or them are as large as ordinary bedding *Hyacinths*. This is altogether such a unique behaviour in the way of bulbs that I thought it worth while to contribute a note about it, and to ask for guidance as to the future treatment? They are potted with the bulbs full out of the soil, and the upper part from which the growth should show is perfectly sound.—H. L. G.

To the following queries brief editorial replies are given; but readers are invited to give further answers should they be able to offer additional advice on the various subjects.

4681.—*The Umbrella-plant (Umbrosa)*.—I certainly cannot answer your query, because I do not know what plant you refer to, so that I am a good deal more of an ignoramus than yourself. It may be that you refer to the *Agapanthus umbellatus*, but I cannot say. Send word again if the flowers are produced in large umbels, and if they are blue in colour.—J. J.

4682.—*Variegated Ferns (C. Elliott)*.—I will devote an article to these soon for your special benefit; but I must tell you in reply to your question that nearly the whole of the kinds of variegated *Ferns* are of the family *Pteris* and that I have seen a variety of one of our common *Bracken*, but it did not retain its variegation. All such variegated *Ferns* are very difficult to maintain upon plants which have a creeping rhizome.—J. J.

4683.—*Lomaria invariata*.—G. B. sends me a much worn root of this plant, which has the appearance of having been blown about by the wind. This is a regular gem from New Zealand, which looks well under a glass in the hall or in the window of a cool room, and I would advise you to fix it up so, making a companion plant of a *Tedea* superior. These look best in a round glass, and this should be a ventilator on the top, when they will make a beautiful ornamental pair.—J. J.

4684.—*Zygopetalum Gantieri*.—*Orchid Lover* asks me about growing *Zygopetalum Gantieri* in a cold house, and on this I would like to remain. It frequently comes home upon the stems of a *Tree-Fern*, and I think that in this position it does the best; but these stems, if dead ones, soon decay and rot away. I therefore advise my enquirer to purchase a living *Tree-Fern* that the plant may have its natural surroundings. It is a magnificent flower, worthy of every attention, and requiring the heat of the *Cattleya* house.—M. B.

4685.—*Oncidium limminghei (G. Boston)*.—This is the name of the flower you send, which you say "creeps flat upon the blocks on which it grows, and is not so heavy." Now this plant is thought to come from Caracas, and belong to the section to which belong the two forms known as the *Butterflies* (*O. papilio* and *O. Krummerlanum*), although the flower is very poor in comparison to these; however, it should be grown upon a block of wood, and it likes the temperature of the *Cattleya* house.—M. B.

4686.—*Stanhopea tigrina*.—*James Bennet* sends me a very nice variety of this plant for a name, which I here give, and I wish to draw attention to the splendid condition in which this heavy flower came to hand. It was packed in a stout box, with no packing, consequently it had nothing to break about in the flower, and it came out as fresh as when it was put in, and I am much obliged to "*Mr. Bennet*." It should not be dried off at once in case it has not finished its growth; but when it has done growing the plant should be kept cool and dry.—M. B.

4687.—*The Rattle snake (Pholidota Imbricata)*.—An *Orchid Lover* asks various questions respecting this species, which I here endeavour to answer. It is an East Indian plant, and it will bear any amount of heat and moisture; of course, less being requisite in the winter season. It comes into flower in the spring months, being white in colour, the blossoms are arranged in a pendulous spike, each flower being enclosed in a thin membranous brood of a whity-brown colour. It should be potted in peat and *Sphagnum Moss*, and the pot should be well drained.—M. B.

4688.—*Oncidium varicosum*.—*Orchid Lover* says this plant of his is now coming into flower. It is true he calls it *Rogers*; but I should like him to send me a flower of it when it is open, that I may verify it if correct. The plant being upon a flat board, which I abhor, it cannot be moved without great injury to the plant, so it should be allowed to remain and to flower; but in the spring it may be set into a pot with peat and *Moss*, and after a time the plant may be worked off the board, and the plant will become established in the pot. It should be kept in the cool-house.—M. B.

4689.—*Bridgetea plicata (R. R.)*.—This, which it would appear more correctly named *Ercilia plicata*, is a *Chilian* plant, introduced upwards of fifty years ago. It has a double flower, which are lobed at the edge, and dark-

grows. It clings after the style of the Ivy, and produces in spring reddish flowers in abundance; but I do not remember ever to have seen it bearing berries. The part you speak of being bare might be covered with Eucyonium radicans, which has the property of clinging to the wall in the same manner as the ivy. It does not require any culture.—J.

4690.—*Gymnogramma leptophylla*.—*De Brock* sends me a few fronds of this plant, which boysay were gathered in Jersey; this being the case, it is the species named above, and it must certainly rank amongst our British Ferns. I am quite aware that the insect fauna of these Channel Islands are not counted as British, but there is just the possibility of their flying from the mainland of France, and with plants which are fixed in the ground there is a difference, and which the ground is British so will the plants be.—J. J.

4691.—*Oncidium Gardneri* (Thunb.).—You should keep this Orchid in the shade, and of the Odontoglossum-house through the winter months, and by no means let the plant become quite dry; but do not keep it in such a wet state as to start it into growth at the dull season of the year, because this has the effect of preventing any flowers appearing. More plants of this and its allied species, such as *O. Forbesi*, *O. crispum*, and others fell through being kept too hot, and too wet through the winter months than from any one thing. You have said the plant quite right, thrive, for only the summer; and if you continue to treat it right through the winter I have no doubt but the growth next season will reward you with flowers.—M. B.

4692.—*Odontoglossum Alexandræ*.—A reader, I suppose without a name, for I cannot find one; however, he wants to know when to report this plant. Well, if it requires reporting, now is about the best time to do it, but it may not require it, and many amateurs are so chary of the reporting system that every year their plants must be reported, until they are reported out of the world; but if the plant does not require it, now it will be better for a top-dressing; to do this, the plant should first be carefully knocked out of the pot, the drainage examined, and made sound, then it may be set back again, and the top soil carefully removed and replaced with new, which should consist of good peat-^{three} and Sphagnum Moss; the surface may consist of the live pieces of Moss only.—M. B.

4693.—*Epidendrum bicoloratum*.—*G. Hill* sends me flowers of this plant, saying if it is not a different variety. But to think of a plant quite so right, for, for I think it is only a plant from British Guiana, in which the sepals and petals are somewhat narrower than in the normal state, and they are more or less dotted with rosy-purple; your spike of seven flowers must be very pretty, but I have seen it producing a spike which had borne twenty-three or four flowers, and this but a few miles from London. This is a difficult Orchid to retain long in coldness, as some of those which come from the influence of the spray from the salt water in tropical countries. It appears, however, to grow very well in very strong heat, but it should be subjected to a good current of air during the time when the sun is brightest.—M. B.

4694.—*Polypodium*.—*K. W.* asks if the kinds mentioned by me some little time back will stand unprotected in the open air through the winter months, to which I may answer in the affirmative, and so also will the *Feris Fern* (*Allosorus crispus*). The finest that I ever saw of this species was in a quarry at Bunkford, but I do not think *K. W.* would be in keeping the British Maiden-hair Fern (*Adiantum Capillus-venusti*) in his neighbourhood. The Wall Rue (*Asplenium Bnt-marrerii*) will grow anywhere if lifted right—that is, it should be taken with the piece of brick or stone upon which it had originally grown intact, and this should be built into the fernery. This species might also be called the Churchyard Fern, for it may be seen growing on many of the old tombstones in almost any churchyard of any age, but in such a place it should be secured. *Woodwardia radicans* is a native of Madeira, and although it does not require much warmth, it will not stand any frost.—J. J.

TO CORRESPONDENTS.

We should be glad if readers would remember that we do not answer queries by post, and that we cannot undertake to forward letters to correspondents, or insert queries that do not contain the name and address of sender.

A. M. G.—The Cherry-tree leaves look as if they had been eaten by a weevil of some kind, but we can see no trace of it now. Also, probably the roots have got down into an unfruitful soil.—*Sotus*.—Use any one of the stores advertised in GARDENING. We cannot recommend individuals.

NAMES OF PLANTS AND FRUITS.

*. Any communications respecting plants or fruits sent to name should always accompany the parcel, which should be addressed to the Editor of GARDENING ILLUSTRATED, 37, Southampton-street, Strand, London, W.C.

Names of plants.—*G. G.*—1, *Deville solidia*; 2, Apparently a *Laucostegia*; too much shrivelled to define. The others cannot name from such specimens.—*C. Franklini*.—*Teoma farnesoides*.—*E. P. L.*—*Cystopteris bulbifera*.—*J. M.*—A form of *Athyrium filix-femina*—*Reynard*.—*M.*—An orchid, send the flowers in a box. When the package came to hand it was in many places, and beyond recognition.—*M. B.*—1, *Asplenium Balanagis*; 2, *Polypodium vulgare canabrium*.—*John*.—*Aspidistra lurida variegata*.—*Coleuraine*.—*Berberis aquifolium*.—*H. U.*—*A. Salvia*, probably *Salvia Heeri*, but specimen dried up a good deal.—*E. Brown*.—*Spartanum atricorne*.

Names of fruits.—*W. H. Woodcock*.—Apple *Crimson Queening*.—*Hussongfeld*.—*Cannet* name the Apple from such a bad specimen. May be a *Craib*.—*Coleuraine*.—*Pear*, Autumn *Immaculate*, Apple, *Beek no-Further*.—*Merrill*.—*Pear*, Winter. *Nella*.—*G. B.*—*Pear Williams*, *Hon Chrétien*.—*Broughshane*.—Apple *Ornish* *Gillflower*.—*Chas. Davies*.—*Apple*: 1, *Cox's Orange Pippin*; 2, *Early Harvest*; 3, *King of the Pipples*.—*C. H. D.*—*Pears*: 1, *Beurré Diel*; 2, *Napoleon*; 3, *Autumn Oranges*.—*Carotus*.—*Apples*: 1, *Yorkshire Beauty*; 2, *Not recognised*; 3, *Hawthornden*; 4, *Wymer*.—*W. G.*—*Pears*: 1, *Beurré d'Amalain*; 2, *Napoleon*; 3, *Cabernet*.—*Apples*: 1, *Beurré d'Amalain*; 2, *Winkfield*; 3, *Beurré Diel*.

Direct from the Growers. BULBS Direct from the Growers. SPECIAL AND IMPORTANT OFFER OF OVER 150,000 CHOICE HYACINTHS AND MORE THAN 800,000 MISCELLANEOUS BULBS.

Carefully compare the following low quotations and remember that I challenge any dealer in the trade, either importer or otherwise to give the same splendid quality at my prices; and, what is more, guarantee to replace next season, absolutely free of charge, any varieties quoted below if the results obtained therefrom are not in every way satisfactory. Buyers should bear in mind that I have supplied for many consecutive seasons some of the largest and best known Private and Public Gardens in the United Kingdom, and that last season, so great was the pressure of business (caused in a great measure by the extreme generosity and disinterested kindness of former buyers in procuring for me over 1,000 new patrons) that I had to withdraw my advertisements, and the same thing will probably occur again as Autumn advances, because it is a fact which no amount of ingenuity on the part of interested persons can dispute, that my prices give buyers an advantage of (in the majority of instances) over 33 per cent, as compared with other dealers' quotations; and those persons who favour me with their orders will be convinced of this fact, which is what many thousands of others have already proved for themselves—viz., that it is an utter impossibility to obtain such splendid value from any other dealer, either in this country or abroad.

Superb Named Hyacinths, for exhibition purposes, packed in my original boxes (now so extensively copied by other dealers), containing 12 distinct and most charming varieties, every bulb guaranteed first class, true to name and specially selected. Included in every dozen will be the following—viz., *Alba maxima*, *La Griensone*, *Partheno Bianco*, and *Baronesse Thuyll* (pure-white); *General Palliser*, *Van Scailier*, *Gertrude*, and *Norma* (reds and pinks); *Grand Maître*, *King of the Blues*, *Czar Peter*, and *Grand Liliac* (light and dark blues), comprising a Collection honestly worth 5s. per dozen, my prices for which are: 1 dozen, 5s. 6d.; 3 dozen, 9s. 6d.; 6 dozen, 18s.; 12 dozen, 36s.; or 30 dozen 75s. Note the enormous reductions for the larger quantities.

Magnificent Named Hyacinths for pots and glasses, really grand bulbs, such as usually sold by others for 10s. per dozen, 12 distinct sorts to the dozen, all named, and containing for outside in every 12s. *La Griensone*, *Alba purpurisima*, *Norma*, *Gertrude*, *Grand Maître*, *Czar Peter*, &c., my prices for which are: 1 doz., 2s.; 3 doz., 5s. 6d.; 6 doz., 10s.; 12 doz., 18s.; or 30 doz. for 40s. Compare these with those you have bought elsewhere at 4s. and upwards per dozen.

Splendid Hyacinths for bedding, the majority of which are quite good enough for potting purposes, consisting of great quantities of *Alba maxima*, and 1200 per 1,000, of charming shades, colours packed separately, and undoubtedly wonderfully good value—viz., 2s. 6d. 1/2; 5s. 6d.; 10s. 6d.; 17s. 6d.; 30s. 6d.; 50s. 6d.; or 60s. per 1,000. Special rates for lots of 5,000 and upwards.

White Roman Hyacinths.—Extra large, specially selected, 25 for 10s.; 100 for 10s.; 1000 per 1,000. Stock almost cleared. Splendid bulbs, as usually sold for first size, 2s. for 2s. 6d.; 9s. per 100; 90s. per 1,000.

Richardia ethiopica, the beautiful Lily of the Nile, or Arum Lily, really splendid roots, the finest obtainable, 6 for 1s. 6d.; 12, 3s.; 25, 5s. 6d.; 50, 10s.; or 17s. 6d. 100.

Lilium candidum (the Old White Garden Lily), direct from the South of France, which has been adapted to flower for certain next season. Splendid bulbs, usually offered elsewhere at from 4s. to 5s., my prices for which are 2s. per dozen; 7s. 6d. for 50; or 12s. per 100.

Tulips.—For all the best-named sorts see Catalogue (free on application). Single scarlet *Duo Van Thoi*, an fine a sample as good as could be had, really splendid bulbs, 2s. 10s.; 17s. 6d. per 1,000; or 5,000 and upwards at 10s. per 1,000. Note these extraordinary low quotations. Double white *La Candeur*, enormous bulbs, the finest in the market, 4s. 6d. per 100; 500, 20s.; or 27s. 6d. per 1,000; or splendid bulbs, as usually sold 3s. 6d. per 100; 50s. 15s.; or 27s. 6d. per 1,000. Double and yellow *Duo Van Thoi*, splendid bulbs, 3s. 6d. 100; 500, 15s. 6d.; or 2s. per 1,000. Double or single Tulips, 1s. extra choice mixture, containing many of the most charming varieties in cultivation, really splendid bulbs, honestly worth 5s. per 100; my quotations here are: 4s. 6d. for 50; 10s. 6d. for 100; 50s. 15s.; 1,000, 20s.; 5,000 at 17s. 6d.; 5,000 and over at 15s. per 1,000.

Freesias.—Reflected silks, splendid bulbs, honestly worth double my price, which are 2s. for 1s. 3d.; 5s. 2s. 3d.; 10s. 4s.; 25s. 8s.; 50s. 15s. 6d.; or 30s. per 1,000.

Snowdrops.—Either double or single, a grand sample, all certain flowering bulbs, not small ones rubbish, 10s. 2s.; 50s. 8s.; or 10s. 6d. per 1,000. *Galanthus Elvire* (the new Glass Snowdrop), 10s. 3s.; 50s. 12s.; or 25s. 6d. per 1,000.

Chionodoxa Lucullæ (Lily of the Snow).—Same rates as *Galanthus*.

Narcissus.—For all the best named varieties see Catalogue, but especially note the following—viz., *Golden Spur*.

NOTE.—The above quotations are strictly nott, and for prompt cash only. No charge whatever will be made for cases, hampers, packing, &c. on orders accompanied by a remittance for full amount, which should in all cases be crossed "London & Midland Bank, Birmingham," all and communications must be addressed to—

J. G. CLARKE, WHOLESALE BULB IMPORTER, 61, PERSHORE ST., BIRMINGHAM.

"GOLDEN OPPORTUNITY." "STREPOSOLLEN JAMESONI" magnificent cool greenhouse plant, easy to grow, trusses 8 to 10 inches across, 2 for 1s. 6d. Also other rare and beautiful plants to give a haze of bloom in winter and spring, greenhouse and garden. All very cheap. Send stamped envelope for List. Don't miss a floral treat. MRS. GARDNER, Fir Trees, STROUD.

MONT BLANC DOUBLE WHITE P.Y. HYACINTH, 10s. per 100, very strong, healthy clumps, 12s. 6d. marked.—JAMES LEITCH, Market Gardens, 12, St. Andrew's, Sale, near Manchester.

one of the largest and most striking *Daffodils* grown, equal to *maximus*, and invaluable for forcing, 12 for 2s. 6d.; 25, 4s. 6d.; 50, 8s.; or 15s. per 100. *Horsfield*, one of the most beautiful of all the bloomers, 6 for 3s.; 12, 5s.; 25, 9s.; or 17s. 6d. per 100. *Bulbocodium Hicop*, *Pasteloch*, 5s. 6d.; 10s. 6d.; 25, 12s.; 50, 21s.; or 40s. 13s. *Ornatiss*, true imported bulbs, the dearest ever offered, 6s. 2d. 1/2; 10s. 4s.; 25, 8s. 6d.; 50, 15s.; or 30s. 1,000. *Principes*, one of the most effective and useful of all *Daffodils* for forcing or cutting purposes, 2s. 1s. 6d.; 5s. 3s.; 10s. 6s.; 25, 12s. 6d.; 50, 22s. 6d.; or 40s. per 1,000. *Pseudo Narcissus*, the English Lent Lily or ordinary *Daffodil*, 10s. 1s.; 25, 3s. 6d.; 50, 6s.; 1,000, 10s.; or 5,000, 40s.

Jonquilla, guaranteed the true sweet-scented variety, 100, 2s. 6d.; 250, 5s. 6d.; 500, 10s.; or 17s. 6d. per 1,000. *Campanula*, 100, 3s.; 250, 5s. 6d.; 500, 11s.; or 20s. per 1,000. *Paper-white*, guaranteed the true *Lotus albus grandiflorus* variety, 50 for 2s. 6d.; 100, 4s. 6d.; or 40s. 1,000. *Double Roman*, 50 for 2s.; 100, 3s. 6d.; or 20s. per 1,000. *Grand* *Mosses*, pure-white with primrose cup, splendid bulbs, 12 for 1s. 6d.; 25, 3s. 6d.; 50, 6s.; or 6s. per 100. *White Pearl*, perfectly pure-white, a lovely flower, 12, 2s.; 25, 3s. 6d.; 50, 6s.; or 12s. per 100.

Crocus for pots, &c.—First also, extra selected bulbs, the finest in the market, assorted, all colours, consisting of equal quantities of yellow, purple, white, and striped, 25 for 1s. 6d.; 50, 3s.; 100, 6s.; or 15s. 1,000. *Splendid Crocus* for bedding purposes, equal quantities of the above four colours, assorted, 100, 1s.; 500, 5s.; or 7s. per 1,000. For *Crocus* to name, or in separate colours at equally low rates, see Catalogue.

Scilla sibirica.—*Splendid* bulbs, 100, 2s.; 250, 4s. 6d.; 500, 8s.; or 15s. per 1,000.

Winter Aconites (the earliest of all Spring Flowers), or *Lily*, in extra choice mixture, exceptionally fine bulbs, 100, 1s. 6d.; 250, 4s.; 500, 7s.; or 15s. per 1,000.

Allium neapolitanum, pure-white flowers, garden in umbels and grown in millions for Covent Garden Market, 5s. for cutting, 6s., 10s. 3s.; 250, 5s.; 500, 10s.; or 17s. 6d. per 1,000.

Iris (Ispanicas). In superb mixture, immense bulbs, the best obtainable, 100, 1s. 6d.; 250, 3s.; 500, 6s.; or 1,000, 8s.

Iris (Anglica), in extra choice assorted colours, as fine a sample as need be desired, 50, 1s. 6d.; 100, 3s.; 250, 6s. 6d.; 500, 12s. 6d.; or 2s. 6d. per 1,000.

Note my low prices for the above Iris; no better quality can be produced.

Anemones.—Finest mixed Single varieties, 100, 12s. 6d.; 250, 25s. 6d.; or 12s. 6d. per 1,000. Finest mixed Double varieties, 6s. 3s.; 10s. 3s. 6d.; 250, 8s.; 500, 15s.; or 27s. 6d. per 1,000.

Lilium Hartii (the true *Bermude* or *Easter Lily*).—An immense collection just received in perfect condition, and better it is impossible to offer. Bulbs measuring from 1 1/2 to 1 1/2 in. in circumference, 6 for 1s.; 12, 5s.; 25, 9s.; 50, 17s.; or 3s. 6d. per 100.

African Tubereas.—Just arrived direct from Natal. *Splendid* bulbs, all carefully selected, 12, 2s.; 25, 3s. 6d.; 50, 6s. 6d.; or 12s. per 100.

For *Lilies of Valley*, *Sprezza*, *Cladidius*, *Lilium nurnum*, and other *Lilies*, *Dioytrus*, &c., due to arrive in October and November, see Catalogue, copies of which will be sent post free on application, but in consequence of the unprecedented demand the supply will soon be exhausted, therefore early application is necessary, as a reseruit is quite impossible.

PERNS 1.—Trade.—Oreat Annual Sale of *Herpida* Block, 100,000, 25 sorts, in 2 1/2-in. pots, stove and greenhouse, at 11s. 100, 200 for 20s. *Strobus* seedlings, 5s. 100, 1s. var. *Large Ferns*, in 4 1/2-in. pots. *Solmsiana*, *Cypripis*, &c., 4s. *A. cuneatum*, large, 6s. &c. *Flora*, *Palma*, *Dracena*, *A. Cavallera*, *Arabis*, 4s. 6d. *Flora*, *Palma*, *Dracena*, *A. cuneatum*, for making leryo plants quickly, 15s. and 20s. 100. Packed free and put on rail for cash with order.—J. SMITH, London Fern Nursery, Lombard-street junction, London, E.W. (Lilium) *TRIMARDEAU* and other *FANSTIES*.—Nice variety plants to stand the winter and bloom early, 3s. 6d. per 100; 2s. 6d. per 100. *F. MILLER*, Made's Elm Wharf, Chatham, Kent.

TREES & SHRUBS

HEATHS IN FLOWER.

THERE are many districts within a short distance of London where the Heaths form a grand feature in early autumn. As a garden plant, however, the Heath and its numerous distinct varieties might be made more use of, not alone in the wild or semi-wild garden, but in cultivated portions thereof, either in beds, clothing a dry spot or sloping bank, as an edging to the larger Ericaceae, or forming a groundwork, from whence specimens of some of its allies may be allowed to spring. In small gardens the Heath lends itself to some effective grouping, as there is a considerable range in height assumed by the different varieties, for the dense little Moss-like forms are, as a rule, from 4 inches to 6 inches high, while some of the more vigorous ones run up about a yard. Not the least attractive feature about the Heath is the time it remains in bloom, not only on the plant, but also when cut and placed in water. With regard to soil it is in no way particular, but where very stiff and clayey, the incorporation of some decayed leaf-mould will be of service, and a top-dressing of the same is of great assistance if it is hot and dry. A walk round any of the nurseries where these plants are grown during the flowering season will reveal the fact that there are several very beautiful varieties, differing not only in stature, but also in the colour of their blossoms and other features. Of varieties with white flowers, there are two or three well-marked forms, notably Searle's, a free-growing kind with large spikes of pure white blossoms. It is later in flowering than most of the others, and in some seasons will continue to bloom till stopped by sharp frosts quite late in the year. Another is alba minor, much smaller growing. This forms a dense mass of quite an erect habit, while rigida alba is totally different, being of a more spreading style of growth, while the spikes of pure white flowers, which are more massive than those of the last, are disposed in an irregular manner. In mentioning pubescens alba, attention may be directed to the peculiar pubescent character of the foliage, which imparts to it quite a greyish hue, so that at all seasons it can be readily detected by this feature alone. This is by no means the only variety in which foliage distinctions play a prominent part, as there are two

YELLOW-LEAVED forms, both very bright and pretty. In one of these, namely known as aurea, the foliage is of a rich golden hue, while in the other it is more of an orange with a bronzy tint. To this last the name of cuprea is sometimes applied. In both the golden hue is much more effective where the plants are fully exposed to sun and air than in the case if they are at all shaded. The variety variegata has white leaves interspersed with those of the normal green tint, and is curious when closely inspected, but by no means striking. A noteworthy form is pygmaea, which forms a dense, cushion-like mass of a rich deep-green colour, and but rarely flowers. It is quite

like in appearance, and as an edging to the others or a rockwork plant is quite at home. The rich tint of its foliage is very different from that of any of the rest. Numerous coloured forms are also in cultivation; a few especially notable ones are Alportii, which is a good companion to the white Searle's, as both are a good deal the same in habit, and they are also late flowering, but in Alportii the blooms are purple. A very bright form is coccinea, white, tenuis is slender in all its parts, but forms a dense pleasing mass with deeply tinted flowers. In habit dumosa rubra is a counterpart of alba minor, except that the blossoms instead of being white are of a purplish-red hue. The last to mention is flore pleno, remarkable from the fact of there being so few of the Heath family with double blossoms, for I am only acquainted with one other, viz, the Australian Epacris onomiflora or purpurascens. In both the blossoms are like little rosettes, those of the English representative being deep-pink, while in its Australian relative they are white. Some of the larger Ericaceae, such as Azaleas and Rhododendrons, have double blossoms, but the above two are all that I can recall among those that can be classed as Heaths. The Cornish Moor Heath, Erica or Gypsoecalis vagans, also flowers somewhat about the same time as the Heather. This is a free, vigorous-growing kind, that reaches a height of about a couple of feet, and bears densely packed spikes of pale purplish-red blossoms. In some the colour is much deeper than in others, that known as rubra being the best. There is also a white-flowered variety, alba. Erica multiflora is a near ally of the above, but the flowers are not borne for such a long distance along the shoots as in the Cornish Moor Heath. In any case Erica multiflora is valuable from the fact that its rosy-red blossoms are produced after those of nearly all the others are past.

4059.—Arranging a shrubbery.—The first thing to do is come to a decision about the main features. Do not plant a meaningless mixture; have a bold group or two, and these there will be more character. Say there is a group of Cedar of Lebanon on or near the edge of the lawn, assuming that the foreground is turf, and the place is large enough for the Cedars to develop. If the place is too small for the Cedars drop in a group of Hollies, including several varieties, which should not be planted nearer to each other than 10 feet. In the background have a Weeping Birch or two growing out of a group of Laurels; the combination is a charming one. The Laurels may be 15 feet apart. If the soil is suitable for Rhododendrons these and Azaleas may be grouped near the edge, and the open place between filled in with the old White and other Lillies, with a group or two of Montrosia in the front margin. A Lawson Cypress may be dropped in here and there to give elevation, and placea might probably be found for Laburnum, Prunus pissardi, Double-blossomed Cherry—the Bird Cherry is a charming background subject—Pam's Double Scarlet and other Thorns, Almond, Aucubas, and the Silver Maple. The Buck-eye-tree should have a prominent place

tion, and one of the most effective plants for the edge of the group is the Venetian Sumach. A few of the Golden Conifers, including the golden form of Lawson's Cypress. A charming group can be made of the Evergreen Barberries, including Darwini, stenophylla, and ampetrifolia, with a foreground of Mahonia Aquifolium, Aucubas—both the variegated and the green are valuable grouping subjects in association with groups of Lavender and Rosemary. Very pretty are groups of White Lilacs springing out of the dwarf Holly-leaved Mahonia. The Guelder Rose, Hydrangea paniculata grandiflora, Pyrus japonica, Ribes in variety, Spiraea arizifolia, Syringa, Philadelphus (or Mock Orange) are all necessary even in a small garden, and the Tamarisk makes a very pretty feature on the margin of the lawn. This is only a rough idea, but no one could give more than a rough idea without knowing the size and the character of the place.—E. H.

—Keep the shrubs away from the front of the house—at least, do not have them just under the window. Plant them at the sides and in groups if the space at command is of sufficient size. The distance at which they should be planted apart depends upon the kinds, but give ample room for development, as all beauty is lost by the "higgledy-piggledy" arrangements so common and disgusting to the majority of gardeners. A small garden may be made as beautiful as a large one in its way if the proper things are selected. Make good use of the Bush Honey-suckle mentioned in GARDENING, October 7. Hardy Azaleas are very beautiful in a peaty or light loamy soil. They flower in June, and the foliage in the autumn is of brilliant colour. The Ceanothuses you might try, especially the variety Gloire de Versailles, which has rich blue flowers, also the Bladder Senna (Colutea), Quince, Cythians scoparius Andreanus (yellow and brownish-crimson flowers), Daphne Mezereum, blooming in early spring, or winter if the weather is mild; Deutzia gracilis; many beautiful kinds of Spiraea, S. arnoux, S. arizifolia in particular; Hydrangea paniculata grandiflora, very fine on the Grass, the heads of white flowers being of large size; Kalnia, in peaty soil; Olearia Haastii; Philadelphus Lemoinei, a dwarf, very free-flowering shrub, with white flowers; Rhododendrons in variety, Flowering Currants, Veronica Traversi, and Guelder Rose, also the Chinese species, Viburnum plicatum. These will, I think, be sufficient for you.—C. T.

4654.—Specimen evergreen trees, &c.—Picea Nordmanniana is a stately lawn tree, and one which preserves its lower branches in complete order for a length of time, especially where the soil is sandy. In stiff soil it does not grow quite so well. Thuja Lobbi will grow almost anywhere and in any soil. The growth is erect, the colour dark-green. Picea pinus glauca is quite one of the best lawn-trees we have where this special tint of colouring is required. Any kind of soil seems to suit it. Cupressus Lawsoniana glauca is another deserving kind; it is merely a glaucous form of the former. In growth it, all that is required. Abies Menziesii is a tall-growing glaucous form of the Spruce fir; it is much more handsome than

an ordinary Fir of the Spruce type. If the soil is light in character, Cedrus Deodora well deserves a place; its drooping habit and glaucous tint of colour would be all that could be desired in heavy soil, though it is apt to lose its "feather" at times. Picea nobilis glauca: This is a fast-growing subject with a distinct silvery-blue hue, quite one of the best of the tribe. Pinus excelsa represents quite another character in trees from the foregoing. It is a handsome subject, especially in sandy soil. Four of the best Maples are japonicum, palmata atropurpureum, rubrum, and planatoides. The chief point in all cases is to prepare the site for each tree well by trenching the soil 3 feet deep, and adding manure to the top spit of soil freely.—S. P.

Cedrus atlantica glauca and Abies Douglasii glauca are both excellent and effective lawn trees, and will thrive well in almost any situation. The Cedar of Lebanon, Picea Nordmanniana, and Pinus can be recommended. Picea nobilis has glaucous foliage, and is a very handsome tree. There are many beautiful trees among Maples. Acer rubrum, A. escharinatum (Sugar Maple), A. striatum, A. laciniatum (Eagle-claw Maple), A. celsibium, A. pseudo-platanus lutescens and alba-variagata are ornamental trees. Then the variegated Ash-leaved Maple (Acer Negundo variegatum) should be in every garden, and the newer Japanese Maples have at any rate proved hardy in sheltered situations, but are too slow of growth to make much mark in the landscape.—E. H.

4648.—Shrubs suitable for a dry situation.—There are not many shrubs that like a dry situation, especially when the soil is full of roots of trees, as probably yours is. Berberis Darwinii and B. dulcis will do as well as any; good bushy and well-rooted plants of the Green Holly, Aucuba, the green and variegated forms of Aucynmas, Cotoneaster microphylla, and D. Simmondii, and Green Box. For the front line the Spanish Gerse will do admirably, as would Veronica Traversi. Before planting you had better pick up the ground, and put some fresh soil round the roots of the plants.—J. O. C.

—The Beech is one of the worst trees for shrubs to grow under. The foliage is dense, and even in winter the drip from the branches is injurious. The most likely things to succeed are common Yew, Green Hollies, Aucuba, Mahonia Aquifolium, Box in variety, Butcher's Broom, Rose of Sharon, Hypericum corymbosum, Ivies in variety, common Laurels, and Periwinkles.—E. H.

—The varieties of Athrea frutescens (Hibiscus sylvanus) are very suitable for a dry, warm soil, but they require a fair amount of sun. The Gum Cistus would also do well, while the Hypericums and Cotoneasters thrive in shady places, and so do Aucuba and some of the Berberis, notably B. Aquifolium.—B. O. R.

4664.—Fast growing Fir trees.—The ordinary Spruce Fir is the best you can have, as it grows rapidly and submits to being pruned or even clipped with shears, if at any time it overgrows on other subjects. You will gain nothing by selecting trees more than 4 feet high to start with. Trench up the ground 18 inches deep and plant two rows 6 feet apart each way. If you would prefer a choicer tree you may select Thuja Lobbi, which is a fast grower and quite hardy, but the Spruce will make the most dense hind.—J. O. C.

The end of October is the best time to plant any of the evergreen Fir tribe, choosing showery weather if possible. If the trees are to be obtained from a nursery they should not be more than 1 foot high, those larger are more likely to suffer from replanting. Many of them may die, as there is a certain amount of risk in planting evergreen Firs. If the trees can be moved from another part of the garden so that a ball of earth can be lifted with the roots, they may be planted up to 6 feet high with safety. Corsican Pine is the quickest growing variety of the Fir tribe. If the position is much exposed to wind the Austrian Pine would be more suitable. Although the latter is considered to be slower in growth than the Corsican, there is really not much difference if the soil is well prepared first—deeply dug and manured.—S. P.

—The Douglas Pine (Abies Douglasii) is very fast growing on fairly good soil. The Scotch Fir is also a fast-growing tree of a different type. Either of these would soon form a hind. I should not have too large ones unless I was quite sure they had been transplanted.—E. H.

4577.—Clematis Jackmani.—Almost any of the large flowered kinds, preferably of the patens or Jackmani type, would be suitable: Miss

France (bluish-purple), Jackmani (purple), and Lilacina floribunda (greyish-lilac), being very abundant in flower. C. moutana (white, flowering in May), is a very free-growing and floriferous kind, and the best of all for covering ngly walls, fences, or trellises of large extent is the common Wild Clematis or Traveller's Joy, which grows luxuriantly, not to say rampantly, in any soil or situation, and soon hides any unsightly object completely with a dense mantle of graceful foliage and flowers. A good dark-red Rose suitable for a cold-house would be found in Andro Schwartz or Madame de Tartas (Tea).—B. C. R.

GARDEN WORK.*

Conservatory.

Now that things are getting settled in their places a bit there is time to look round and see if any insects are present, and if a green-fly or thrips, mealy-bug or scale exists anywhere under glass, take no rest until the fact is exterminated. One thing may be noted. Fumigation, though destructively to green-fly and thrips, does not injure mealy-bug or scale; therefore insects must be attacked with the sponge and strong washes. A strong solution of soft-soap is as cheap and good as anything. Reduce the climbing growth as much as possible; all the light will be wanted now. Winter flowers, such as Hebe themnus elegans, Aubletias, Lapagerias, Trachelium Fireball, &c., will be allowed to develop; the last-named is a very useful winter-flowering plant, and may be allowed considerable freedom of growth. Basket-plants, especially Ivy-leaved "Geraniums," will still be effective. One of the best, if not the best, is still the old pink variety, Maree Creuse. With me it grows and flowers all winter in a warm-house. Zones "Geraniums" specially grown for winter bloom will now be a special feature, but to keep in good condition they must have light and warmth as the flowers damp so much in a cool-house, but if kept growing in a slight temperature of 55 degs, with a corresponding increase during the day, they will continue to grow and flower all the winter, or, at least, till after Christmas. There are some pretty things in Salvia now, all of which are easily grown; Brunell, Fitzheri, and aurea are good. Sparmannia africana is a useful subject either for pot culture or to plant in the borders of large houses. Forcing shrubs and roots should be placed under cover now. A cool-house or pit is the best place for them for the present. Rhododendrons with buds may be lifted from the beds and potted, and be brought on kindly by-and-by. After Christmas we shall have to depend largely upon forced flowers; at present there are plants of forced flowers which have been naturally grown, and the Chrysanthemums will be a show of themselves by-and-by. Continue to give stimulents till the flowers are nearly expanded, then discontinue it. As Zuberous Begonias go out of blossom move to a cool-house and give less water to gradually ripen the growth. Fuchsias which are no longer effective may be taken out to a cool-house also. Show Pelargoniums must occupy a light position in a buoyant atmosphere to keep the foliage strong and healthy; this alone will deter insects from attacking them.

Stove.

Poinsettia will now be showing their scarlet bracts, and will be in full bloom. Cyclorhizas and other autumn-flowering plants will be coming on. Gardenias, Eucharis Lilies, and Begonias will add their quota to the beauty and fragrance of the stove. These plants which have done their season's work will require less water, so that they may gradually get rest. Among the latter will be Gloxinias, Achimenes, Caladiums, and the summer-flowering shrubs, including Clerodendrons, Alamanias, Ixoras, Dipladenias, &c. This work of resting should be a gradual process, so that the maturation may be perfectly carried out. Discontinuation is necessary. Gloxinias and Achimenes will be quite dried off; but the ligneous subjects must not be so dried as to injure the vital powers of the plant. We must not treat all subjects alike, or mischief will be done. Pancratiums are beautiful autumn-flowering bulbs, and are not difficult to grow well. As they go out of flower give them dryer treatment. Gesnerias will now be a special feature, especially the Onocnabites section. These are not difficult to raise from seeds, which should be sown early in spring in brick pans, and pricked off into pans filled with peat, leaf-mould, and sand as soon as large enough to handle. Among plants so able for dinner-table decoration are Crotons, especially the Angustifolius section, having long, narrow leaves, which fall over gracefully. Small plants of Asparagus plumosus are always useful, and the long, well-furnished sprays are charmingly effective on the cloth, or to form arches across the table, and they are fairly long-lived. Cyperus alternifolius variegatus, and several of the light, elegant variegated Grasses, such as Eulalia japonica variegata, and the variegated forms of Carex japonica, will be found very useful. Among Palms Coccos Weddelliana is one of the most serviceable, and it does well in the room. Kentias, agala, Euterpe edulis, and Geonoma gracilis are desirable plants to have in stock. Temperature should be steady now at night, 60 degs. to 55 degs. Fire-heat should always be associated with sufficient moisture in the atmosphere to keep down insects and secure healthy growth.

Ferns under Glass.

The advantage of cool treatment in summer will now be manifest in strong, hardy fronds that will set in a cut state, and such plants may be taken indoors without injury. Ferns are in many places too much shaded in summer to be of much use for indoor decoration. A few small plants of Lygodium scandens will be found useful for trailing about, and Geopelia Ferns, Davallias and others in baskets will always find a place, though they cannot easily be impro-

* In cold or northern districts the operations referred to under "Garden Work" may be done from ten days to a week later than is here indicated with equally good results.

vised. Mosses (Selaginellas) are now a very large family, many of which see very elegant when well grown, and are exceedingly useful in small pots or in small pans. It is not advisable to repeat specimen Ferns at this season, but young plants may be shifted on if it is desired. I am continually potting on seedlings and young stuff generally as room is found for them. I would rather pot on now than keep things starving in small pots all winter. Tropical Ferns will do new in a temperature of 80 degs, and greenhouse varieties will do in about 45 degs. to 50 degs. Ferns will bear more heat, but it is only wasting fuel.

Hard-wood Plants.

Among these is plenty of blossom in winter. Camellias will soon be coming in, and forced Azaleas are now showing colour. Heaths, Epacrias, Cherezamos, Correas, Genistas, Daphnes, Ericaceums, Lechoenanthias, Lonicas gratiolinas bloom naturally in winter. If I were a rich man I should be in vigorously for these hard-wood subjects. Our gardeners would soon get into the knack of growing them again. They went out of fashion when it was found they could not be treated to much account in brightening up the dark places of the house on party nights; but they are worth growing, even to look at when in bloom in the conservatory.

Cold Frames.

These will still be filled new with something or other. Seriously anybody beset with these small portable frames, which can be made to be useful work either on a heap of manure or in a cold-house, will find that a lot of spare lights will be found useful now for sheltering Strawberries intended for forcing in pots. These should be plunged in ashes to the top of the rim of the pots, and sheltered with spare lights they will get all the rest they need, and be exposed at the same time to a free circulation of air.

Mushroom-house.

Mushrooms are now being gathered freely from open-air beds; but for a winter supply there should be a properly-constructed house, heated with hot-water pipes. It will not always be necessary to use fire-heat, but there should be the means of doing an if required. So much produce can be obtained from the Mushroom-house other than mushrooms. It should find a place in every garden. Not that it is too commonly used, but the result is a sturdy structure, built as well as possible, where it cannot be much influenced by the summer heat or the winter cold.

Window Gardening.

The time has come now for clearing out window-boxes, and filling up with plants for winter and spring. I consider the shrubs used in window-boxes to be decidedly expensive from being too large. Small, well-grown shrubs, from 9 inches to 12 inches high, are more effective than larger plants, especially if the latter, which is often the case, are not so well grown. Common bulbs, Snowdrops, Crocuses, Lent Lilies, and Tulips, are charming to mix with the shrubs. Autumn-sown annuals make pretty masses in spring, and will come off in time for the "Geraniums," &c., and they have the merit of cheapness.

Outdoor Garden.

Alterations which involve the removal of shrubs and turf may be done now. It is true the soil at the time of working is very dry; but if before these lines are in type rain does not fall till the shrubs and trees have a good soaking of water a day before removal, and they must also be well watered during the process of planting, and generally fill the roots of the tree as shrub carefully in the hole, and partially fill it up, then give enough water to moisten all the soil; the remainder of the soil can be filled in when the moisture has drained away. If the holes are left upon till next day no harm will be done. No matter at what season the planting is done, it is important that the roots should be settled firmly in the soil, and I think water does this more effectually than pressure alone. I have seen several remarkable instances of the value of this system of planting during the present season. The trees puddled, if I may so term it, have done well, whilst others planted in the ordinary way have failed. The facerated roots of evergreen and other trees and shrubs should be placed in a position to commence repairing damage as early as possible, and placing them in contact with moist, firm soil is the best arrangement for that purpose. Tender bulbs and tubers should be taken up, dried, and stored away. The refuse to Dahlias, Gladioli, Tuberoses, Begonias, Marvels of Peru, Salvia patens, and Tigrids, Caenas, especially the new dwarf hybrids, are very useful for mowing, and, if covered deeply with litter, they may remain out all the winter; but the mounds of litter are usually very objectionable in a conspicuous position, so that usually the Caenas have to be lifted. I have kept them packed closely together on the floor of the orchard-house; but they may be kept quite safely in a cool-house where the frost is kept out. Outrage of evergreen shrubs will strike now in a steady bed, kept moist.

Fruit Garden.

Late Melons must have heat if they are to ripen properly; if no frames, a warm linax of manure will enable the plants to finish off the crop; but it is useless to think of growing good Melons after September 15th. They want more buoyant atmosphere than can be secured on a dung-bed. A small open-roofed house heated with hot water will produce good Melons up till November; afterwards they are of inferior flavour, and those who know what good Melons are will not touch them. Those who desire novelty in the way of dessert may grow the Geneva; the plant is an evergreen, and bears freely when some else has been obtained. The fruit commences to ripen towards the end of the summer, and continues through the autumn if not forced much. May be grown as a bush, but succeeds better trained within a foot or so of the glass, after the manner of Peaches. The same kind of border in which Vines or Peaches are planted will do for Guavas. Should heavy rain set in Strawberries in pots intended for early forcing will be better laid on their sides for a time, but should not be permitted to get drier; but plants in good-sized pots will not dry so soon now. It is a mistake, I think, to use smaller pots than 32 or 40 inches diameter for Strawberries. For late gathering 7-inch pots will be better. There is always the danger of the plants in small pots not getting sufficient water, and the fruit from a dried-up plant is useless. Root-pruning over-hurriedness may still be done, and Vines which are growing in sour, peaty borders should be lifted at once, and the roots be kept in a dry place till the foliage.

Vegetable Garden.

Take up and store Beet and Carrots; they keep best packed in sand. Parsnip and Salsify will keep best in the ground for some time yet. Late Potatoes will be better lifted now; store in rather small hills or clumps. There is a wonderful crop this year of the late sorts, and the tubers are sound for the most part. It is best to separate seed from the ware before storing. As regards saving the seed, there is much value in selecting from the most prolific roots. Like will, in a general way, produce like, and sets saved from a prolific plant will produce a heavy crop next year. Finish earthing up Celery when the weather is dry. Tie up Endives and Lettuces in succession to blanch; severe frost will do injury to both these plants when lolly grown, hence the success by protection in frames or placing a thick covering of dry leaves or Ferns over the plants when blued up to blanch. Beds of Lettuces and Endives have been kept in good condition a long time, when the space between the plants have been filled in with dry leaves, and a sprinkling of dry Fern scattered over to prevent the leaves scattering. This is a better and cheaper way of keeping full-grown Lettuces than lifting and planting in frames. If heavy rains set in after the plants have been filled in with leaves, draw a light waterproof cloth over the beds; oiled calico will do. Remove all exhausted Peas, Beans, and other crops, and trench at every favourable opportunity. The late hot summer must have taught the shallow cultivator a useful lesson. For vegetables the land cannot be too deeply stirred, and there can be no good culture without manure.

E. HORDAT.

Work in the Town Garden.

The interest of the gardener, amateur or professional, now centres itself chiefly in the Chrysanthemums, of which the blooms are in many cases fast expanding, and promise well for a grand display of colour shortly. After all the flowers will not be so very much earlier than usual,

pot. Spiraea, Deutzias, and other hardy roots for forcing should also be potted and plunged in ashes or fibre in a cold frame as soon as they can be obtained. Take cuttings of shrubby Calceolarias, inserting them in a cold pit or frame. Plant out Carnations, and fill vacant beds with Hyacinths and other Dutch bulbs.

B. C. R.

THE COMING WEEK'S WORK.

Extracts from a garden diary from October 14th to October 21st.

Pruned Vines in early house; the leaves were not quite all down, but the wood is very ripe and firm. The house will be thrown open now night and day till the middle of December. My first drops of Grapes are taken from pot-Vines, and these are now pruned and standing outside to give them as long and complete a rest as possible. The pot-Vines will not be started before the end of November, but they will be pushed on faster than would be desirable with permanent Vines, as, after fruiting, the plants will be thrown away. Mushroom-heds made outside in August are now coming into bearing. Open-air heds must be sheltered from heavy rains at this season; a waterproof cloth is the handiest thing, as it is so easy put on and taken off. The beds are covered with dry litter, and the cloth afterwards drawn over. It is absolutely necessary to keep off cold rains at this season and onwards through the winter. Beds are being made up in the heated Mushroom-house now, so that it will not be necessary to make up more beds outside. A well-constructed Mushroom-house is very useful for forcing other things besides Mushrooms. The greater part of my Sankale and Rhubarb are forced in the Mushroom-house, and there is no better place for blanching Endive, or Dandelions quickly or forcing Chionodox when the Endive gets scarce. I have forced early Asparagus in the Mushroom-house, moving it to a warm house to get colour and flavour. I have just

PLANTAIN LILIES (FUNKIAS).

THESE are hardy perennials of the handsome type, and it is not alone for their bell-shaped flowers that many cultivate them, but also for the characteristic foliage, which in some kinds is as massive and noble as that of a tropical plant and in others delightfully variegated. The Plantain Lilies are liliaceous plants, and are very effective when planted in large clumps, as we may sometimes see them in the London parks and gardens. Nothing could be more striking or tropical in aspect than a mass of *F. Sieboldi*, which is represented in the accompanying engraving, and clumps on the border, and higher and rougher parts of the rockery have a peculiarly beautiful effect, as much from the silvery glaucous colour of the leaves as from their width and vigour. The several varieties that have variegated leaves are also exceptionally pretty in small groups, as edging to large beds, or for the margin of the rockery. At Kew the variegated kinds are planted with admirable taste on the rockery, where during the summer their variegated leafage of white and green is conspicuously handsome. There is no garden but can find space for either a clump of the hold-growing plain-leaved type or the variegated forms, and the latter may also be potted up for the enrichment of the greenhouse with advantage. One point is easily overcome, and that is the cultivation. A well-drained, deep soil will grow the finest specimens, and if an increase of stock is required, the simplest way is to propagate by division of the crowns in winter or in the spring. The latter season is the best, just when the plants are commencing to make new growth. It is scarcely necessary to add that only well-established thoroughly healthy clumps should be divided, and then they should not be split up into single crowns.

F. Sieboldi is one of the best known and most striking of all the Plantain Lilies, the accompanying engraving of it showing its character remarkably well. It grows from 18 inches to about 3 feet in height, and has very large heart-shaped glaucous leaves that measure quite a foot across. The flowers are white, tinged with pale lilac in colour, and borne from ten to fifteen in tall racemes. This noble species came from Japan in 1836.

F. GRANDIFLORA is an exceptionally beautiful Plantain Lily, and should be extensively grown for the sake of its spikes of snow-white deliciously fragrant flowers. The large hold leaves, as broad as those of *Sieboldi*, and delicate pale-green, make this one a strikingly handsome plant without the flowers. On light warm soils it does well and even blooms satisfactorily, but usually the flowers are cut off by frosts, and it is thus necessary to grow the plant in pots to obtain it in its full beauty. Tufts of it in well-drained beds and borders are not common in English gardens, but it may be grown in this way, and in Paris it is used with much success. I advise *Enkia grandiflora* to be grown freely where flowers of sweet scent and delicate colour are required in autumn. It is the same as *F. japonica*.

F. FORTUNEI is a very robust species, growing about 1½ feet in height. Its leaves are smaller than those of *Sieboldi*, and they have a distinctive bluish or glaucous tint. Another handsome species is *F. subcordata* that has several synonyms, as *Hemerocallis alba*, *H. cordata*, *H. japonica*, and *H. plantaginea*. It is an August flowering plant, with heart-shaped leaves about three quarters of a foot long and 5 inches broad. They are glaucous on the upper surface, but pale-green beneath, and have large prominent ribs than in *Sieboldi*. The growth is quick, and a spreading clump in a garden is magnificent, as the noble leafage is very dense and handsome. There are two variegated varieties, *marmorata* and *argentea*, that are prettily marked. *F. ovata* is the commonest of all; it is an old garden plant, and found in China and Eastern Siberia, besides Japan. The leaves are broad, rich-green, and the flower-stems about 1 foot or more in height, the colour of the flowers being white, tinged with lilac. It is a robust grower, and soon makes a spreading mass. Those who use for variegated foliage will find the variety *marginata*, in which the leaves are distinctly margined with white, a good type of its class.

F. LANCIFOLIA is the species that may be

Siebold's Plantain Lily (*Funkia Sieboldi*).

though in this respect there is a good deal of difference. One effect of the extremely hot and dry season is seen in the comparatively short growth of the plants, and another that in many cases where the supply of water has not been as liberal as it should have been is the bare appearance of the lower part of the stems, owing to the leaves having fallen. As long as the weather remains mild free ventilation must be given, and a gentle warmth should be maintained in the pipes—by night, at any rate—in order to dispel damp, which otherwise is sure to be troublesome. The larger, fuller, and more perfect the flowers the more liable they are to injury from damp. Many of the best Japanese varieties expand best with the aid of a gentle warmth, but the cooler the incurved flowers are kept the better, so long as the petals remain dry; these must also be kept comparatively close to the glass, or they will not expand well. Of course, all must be given freely on all fine mid days, and the watering be carefully and regularly performed, this being best, or chiefly performed in the forenoon. Too little moisture at the root will be less injurious than too much now that the plants are housed. When grown expressly for show purposes backward blooms may be hastened to some extent by the use of a moderate degree of heat, and also by the judicious employment of quick-acting stimulants, such as sulphate of ammonia. Others may, if necessary, be retarded by keeping them cooler, with plenty of all day shade from sun. Keep all suckers removed from the base of the plants until the blooms are fully expanded. In the case of new or scarce kinds they should be inserted as cuttings, if only for stock purposes. No time must now be lost in getting plenty of Hyacinths, Tulips, Narcissus, and other bulbs potted or boxed, as the case may be. For supplying out flowers it is a much better plan to plant all such things thickly in boxes 4 inches or 5 inches deep in any good light soil. They occupy far less room than pots, and are easily carried from place to place. Such boxes must be well covered up with ashes for six or eight weeks in the same way as

about finished earthing up the late Celery. I like to get this work done during October; after the soil gets wet and sticky the work cannot be done so well. Took up Carrots and Beet; all late-sown Carrots, and which are still growing, will be left in the ground, and be covered with dry Ferns about frost set in. A layer of dry Oak-leaves, if they are down in time, will be placed under the Ferns. I find these Oak-leaves very useful for sheltering many things when dry Fern is placed over them to prevent the wind blowing them about. Pricked out August-sown Cauliflowers in cold frames; shall give all the air possible when not wet or frosty by drawing off the lights. Violet-frames are served in the same way when mild and not damp. A close, stuffy atmosphere is not good for anything. Looked over late Grapes frequently, and if a decaying berry is noticed it is at once removed. Dead leaves are also promptly gathered up, and every stray leaf or shoot which is near the glass, and which is likely to form conductors to the moisture condensing on the glass, are removed. Grape-growers know the mischief done in this way when the Vines are trained near the glass. Everything in the vinery should be sweet and clean, and if the Grapes are to hang long plants should, as far as possible, be kept out. I never bottle Grapes till I want to prune the Vines. Busy clearing beds in flower garden, and filled up with spring-sowing things. There is no lack of variety in the plants which may be pressed into the service of the spring garden; even the amount to be expended is small. To make a large display of bulbs costs money, but Wallflowers (yellow and red), Forget-me-nots, Daisies, and Primroses are cheap, and these I use largely. Just finished housing the Chrysanthemums. The early varieties have been under cover some time, but it is desirable to keep late sorts as long as possible; but when plants are exposed to sharp frost the buds suffer and the flowers cannot be so fine. Transplanted evergreen shrubs and turfed over the borders which surround the beds of shrubs; but all the bulbs in the borders will be left to grow as they please.

recommended for the fronts of beds, borders, and rockeries, as it is a small-growing plant, the leaves each about 4 inches long, sometimes more, and only measuring about 2 inches wide; they narrow considerably towards both ends. The raceme of flowers is comparatively short, and does not stand up boldly and gracefully as in the other kinds. Of lancifolia there are two beautiful variegated varieties which should be grown. These are albo-marginata and undulata variegata. In the first of the two the leaves are margined with white, and in the other the edge is wavy and the leaf distinctly variegated.

The above-mentioned species and varieties comprise the richest gems of this genus. I may add one thing more, and that is the suitability of the noble Sieboldi for town gardens. For years there were two wooden tubs which stood in a front garden in Holloway, each containing a magnificent clump. Although exposed to the dust, dirt, and heat of a London garden, the leaves were as broad and rich in colour as in the choicest specimens grown in the pure air of the country. D.

ORCHIDS.

HARDY LADY'S SLIPPERS.

THIS section is scarcely less beautiful than that containing the tropical species, from which the hardy kinds are readily distinguished by their herbaceous habit. One of the freest and most vigorous of the whole group is the white-flowered rosy-lipped *C. spectabile*; and *C. pubescens* and *C. humile* seem to do much better than any of the others, if we except *C. Calceolus*. The majority succeed tolerably well for a year or two in a cool, moist peaty compost; and, if grown in pots, they should be plunged in a cold frame with a northern aspect, and protected from the mid-day sun. *C. spectabile* may be planted out in a border of peat and leaf-mould where it will flower several years in succession if kept regularly moist and cool at the root. *C. Calceolus*, on the other hand, prefers a strong chalky loam with an eastern aspect, sheltered on all sides from rough winds and sun. If these hardy Lady's Slippers are grown in pots, they should be well drained, as has just been recommended; and, if syringed every morning, so much the better. The pots should be surfaced with fresh green Sphagnum to prevent undue evaporation from the soil, such surfacing also keeping the soil cool by acting as a non-conductor. The roots should never be allowed to become dry, even in winter—an evil to which may be attributed the loss of many of these interesting plants. A collection of these hardy species, planted in a peat border outside at the back of a Heath house, used to grow well in Messrs. Rollinson's nursery at Tooting. During winter and spring they were protected by a layer of Sphagnum 2 in. to 3 in. in thickness. The following are the kinds usually grown:—

C. CALCEOLUS (common hardy Lady's Slipper).—This is one of the rarest, and also one of the most beautiful, of our native Orchids. It grows about a foot in height and bears one or two showy flowers at the apex of the strongest leafy stems. The sepals are of a deep purple tint, the petals being narrow and tapering with wavy margins. These are also of a purple colour tipped with yellow at their apices. The lip is rounded or swollen, and being of a clear golden-yellow colour, contrasts well with the dark sepals and petals. It is found in woods in Russia, Asia, and Eastern Europe and the Arctic Circle, but is more sparingly distributed over Western Europe; in Britain it is almost, if not quite, extinct. One of the best-known habitats of this plant was Castle Eden, Dean, Durham, and it has also been found in Yorkshire. According to Thunberg, it is also a native of Japan.

C. PARVIFLORUM (Small-flowered Lady's Slipper).—This has been more than once referred to the last-named species, from which, however, it is readily distinguished when both are seen side by side. The plant is similar in size and habit, but the lip is larger and distinctly flattened or even depressed in front, and the flowers are also delicately perfumed. The sepals are of a rich chocolate-brown colour, while the slender, wavy, or twisted petals are green at the base and streaked and spotted with dark brown. The lip is of a clear yellow colour, with a row of

crimson or reddish dots around the mouth. The leaves are of a fresh apple-green. It is a native of Canada and probably of North America.

C. PUBESCENS (Hairy Lady's Slipper).—This is a free-growing species, both stem and foliage being covered with whitish hairs. It is very distinct from both the last-named kinds, and grows well treated as a pot plant in a shady cold frame. The sepals are of a creamy yellow colour, striped with bright red; petals narrow, very much twisted, also yellow streaked with red, while the lip is of a clear golden tint. In shape the flower reminds one of that of *C. Calceolus*, but it is readily distinguished from that

Flower of *Cypripedium gottatum*.

species by the yellow sepals and twisted petals, and also by the flower being scentless. It is a native of North America.

C. TRAPEZANTUM (Pelican-flowered Lady's Slipper).—This is a very fine large-flowered species. In shape the flowers resemble those of *C. spectabile*. They are fully 4 inches or 5 inches across the fully-expanded segments, and are borne one and two together on the leafy stems. The colour is a bright golden-yellow throughout, and the lip is blotched within with bright reddish-ochraceous, and in shape reminds one of some of the large-flowered Calceolarias. It is a tender species. It requires plenty of water at the root when growing, and an airy atmosphere suits it better than a close one. It is a native of the Savanahs, or great natural meadows of Upper Mexico, where it is found at an elevation of from 2,000 feet to 5,000 feet.

C. MACRANTHUM (Large-flowered Lady's Slipper).—This grows from 6 inches to 12 inches in height, and bears one or two rosy-purple flowers at the apices of the stems. The petals are striped, and the lip, which is inflated, is distinctly netted with dark veins. It is a native of Siberia, and is well worth general culture.

C. VENTRICOSUM (inflated Lady's Slipper).—This is another rosy-purple flowered species, much resembling the last in general appearance, but easily distinguished from it by the petals being shorter than the lip, a very unusual occurrence in this genus. The lip itself is shaped like that of *C. macranthum*, but it is of a much deeper colour. It is a native of Siberia.

C. SPECTABILE (Showy Lady's Slipper)—figured on page 445—is a very beautiful hardy species, and one which succeeds well planted out in a cool peaty compost, sheltered from the midday sun. It also makes a splendid pot plant plunged in a cool and partially shaded frame. The stems rise from 1 foot to 18 inches in height, and bear from one to three large flowers at their apices; both leaves and stems are covered with short white silky hairs. The flowers, which each measure about 3 inches across, are of pearly whiteness, the rounded lip being suffused with bright rose around its mouth. It is a native of the United States and North America, and should be grown in every collection of moisture-loving hardy plants.

C. GUTTATUM (Spotted Lady's Slipper).—This charming little plant resembles *C. acule* in habit, but has snowy flowers blotched with purple. The whole plant is only a few inches high, its short stems being two-leaved. It is a

native of Siberia, North America, and Northern Russia, where it grows in swamps and spongy bogs.

C. CANDIDUM (Milk-white Lady's Slipper).—A pretty little species, similar in habit to *C. spectabile*, growing about a foot high, and bearing a solitary flower at the apices of its leafy stems. Its sepals and petals are white or greenish-white, more or less streaked and shaded with pale brown. The lip, which is inflated, is pure white. A native of boggy marshes, and extending into Canada to the northward, and to the Plateau and Rocky Mountains to the west.

C. ARIETINUM (Ram's-head Lady's Slipper).—Botanically, this is remarkable as being the only species with free lateral sepals, and this character serves to distinguish it from all the other species at present introduced. The lip tapers from the mouth to a blunt point, the colour being white, curiously chequered with bright rose, like some of the Fritillaries. The upper sepal is ovate, the lower sepals and petals being nearly linear, of a dull green colour streaked with reddish brown. The flowers, which are solitary, scarcely measure an inch across and are not showy, although the plant is worth culture where variety and botanical interest are appreciated. Native of Canada.

C. ACULE (Stainless Lady's Slipper).—This is one of the commonest of hardy Lady's Slippers, and is frequently met with in good collections of hardy plants. Treated as a pot plant in a cool frame, it does remarkably well, and blooms freely every spring along with *C. Calceolus*, *C. spectabile*, and *C. pubescens*. It grows well in an open compost of spongy peat, and, like its congeners, must have a copious supply of water at the root. The whole plant is 6 inches or 7 inches high, having two broad green leaves at the base and a solitary nodding flower, borne on a slender scape. The lip is rosy-purple, netted with darker veins and curiously folded inwards in front. It is sometimes known as *C. humile*. J.

LELIA PURPURATA.

I AM requested by "G. Watson" to give him some information about this species; he says that after flowering it has now again started into growth, and is rooting very freely. Well, this is just as I have found them to do with me, and it is what I like to see them do, because now is their season of growth, and therefore these plants, which are unlike *C. Downiana*, and its variety *aurea*, and the *C. gigas* set, do not require to be kept quiet; at the same time, they require to be nursed along carefully and not forced, and they will move but slowly until the turn of Christmas. These plants should be moved into a position in the house where they will get about 5 days more heat than the other occupants of the Cattleya-house; they will also require more care in the way of watering, taking particular notice not to use the syringe to these plants at all, or the water will run down the stems and get into the shoots under the sheaths, and work great havoc amongst the young shoots; but during the beautiful bright sunny days which we are getting now through the month of October the stages between the pots may be kept nicely moist, and do not let them get dry at any time during the winter, but keep the plants in a happy, comfortable state, and they will go on quietly and swell up their growths, finishing them off in the early spring and making a sheath in each, from which will issue their beautiful blooms.

MATT. BRANBLE.

ONCIDIUM TIGRINUM.

THIS beautiful flower is called by the natives of Mexico the "Flower of the Dead," which was given it by the Spaniards that invaded and overran the country, and who used it for funeral purposes; but "Mrs. Duncan" will not take it amiss that the name is used here in connection with a plant she writes to me so pleasantly about. She says she has three plants, which she has grown quite cool, and she has now five spikes of flower showing upon them. These plants have been grown for nearly two years past in hanging-baskets near to the glass, and have had plenty of water; and now "Mrs. D." says how shall she treat them, that they have apices showing? Must she withhold water and rest them? Certainly not, and no Orchid that is coming into flower, springing up into new life, wants to be

put to rest and dried up, and to speak the truth this is a plant that does not require drying at any time, and the fact of its having large bulbs does not afford any clue to its being used to it naturally, and the largeness or the reverse of the bulbs of any Orchid, I have come to the conclusion, has nothing to do with its waste and requirements. This plant comes from various parts of Mexico, and it thrives admirably in a cool-house; but it likes an abundance of fresh air, which is a point I should like to say a word upon, as in several gardens this season I have forced the air of the Odontoglossum-house close and stuffy, and nearly as hot as the Cattleya-house seed bed. Now in all these places the Odontoglossum have not thriven well. The plants have thin leaves and poor bulbs, and when the flowering season comes round I fear they will show a still greater falling off, and the usual outcry from the parties treating their plants in this way has been that the heat was so great that it would have hurt the plants so to admit air, which, to some extent, was true, no doubt; but this could have been avoided by reducing the quantity of air admitted and increasing its moisture by damping down the stages and the floors more frequently, and by having the house shaded with a raised blind. This is an invaluable aid to keep the house cool in hot weather. Then, again, the Odontoglossum would have been greatly benefited by increasing the ventilation through the summer nights, for I am greatly opposed to the system of shutting the houses up close when night comes round, for it is like wishing to teach me that the plants live naturally for half their existence without air, and I did for years have ventilation upon my Orchid-houses at night, except upon a few exceptionally severe winters, when air was only kept from the plants by necessity. Some of my fellow-growers used to laugh at me, but my plants showed their appreciation of the treatment by flowering better, and by always having a cheerful appearance. But to return to my subject of consideration, the *Onodioidium tigridium*, which was first brought to this country by Mr. Barker, of Birmingham, more than fifty years ago, and it was named by Lindley after its introducer. It remained a scarce plant for some time, but then our houses were kept hotter and the plants were subjected to a regular system of resting, which did not encourage their growth, and the plant became nearly extinct. To Mr. Sander, however, we are indebted for its re-introduction, and now we know that it does not require more heat than the Princess of Wales *Odontoglossum*, and that it does not require any dry season. It should be thoroughly drained—indeed, this is the great feature in plant culture—using for soil good brown peat-fibre, mixed with chopped Sphagnum moss, pressed down firmly.

MATT. BRANBLE.

HOUSE & WINDOW GARDENING.

4573. — *Azaleas in a window.* — Azaleas are not good window-plants unless treated very carefully, for the reason that window gardeners do not understand that the plant must make a certain amount of new growth every year, and which must be well ripened, or it will not form flower-buds. The best treatment after it has flowered is to keep it inside the window until the new-made growth is an inch or more in length, and remain there until the flower-bud is quite prominent. Until this is seen it is not right to put the plant outside at all. After this date it is not safe to leave them outside at night, and only in the day when it is warm. When I tell you that the Azalea is a native of India you will understand that it requires rather warm treatment.—J. C. C.

— If the Azalea is of the Indian section by all means bring it indoors at the approach of frost; it will be all right for the winter in the window of any room where no gas is burnt, and where frost cannot easily enter. The dry heat of a kitchen would be injurious, and dust and draughts should also be avoided. Take care that the soil and roots do not become very dry at any time, but at the same time no water should be given as long as the soil remains moderately moist.—B. C. R.

4604. — *Marguerites for a room.* — Both Yellow and White Marguerites can be grown in a room without gas during the winter, but the

plants should first be planted out in the border during the summer months, when they become very strong, and are covered with buds at the present time. They should then be cut round with a small sharp spade at a distance of 4 inches or 5 inches from the stem of the plant, and a week later carefully raised and placed in a good-sized pot, with plenty of drainage and rich, light soil. The plants should then stand on a bed of ashes against a north wall until they have lost all inclination to droop (well watered if the weather be dry), when they may be lifted into a sunny window, where they will bloom for months. But if "M. Y. L.'s" Marguerites are in pots already, and have exhausted the soil, they might receive a shift now, giving them a good fresh compost of loam and leaf-mould, with a little soot and sand, and if allowed to stand in the open air to harden, until sharp frosts make their appearance, they would be all the better for it, and will probably flower well in the spring if they only bring a few blossoms now. Nearly all room plants should stand out-of-doors for three or four months in the later summer; the weakening effects of room culture can thus be minimized, and they will have a chance to ripen their wood and become hardy, for no plant can blossom well with soft, sappy growth. If the Marguerites are leggy and untidy, it is best to propagate them by cuttings early in the year (or even now), covering them with a bell-glass for a few weeks, or placing the pots of cuttings in a box, standing on a layer of damp ashes, covered with a piece of glass. They are easily struck in this way, and if potted on, and given plenty of fresh air and sunshine, will make neat little plants in the spring. They should be pinched back a few times, and not allowed to bloom until they are about 10 inches high, when they should make handsome, bushy little specimens.—I. L. R.

4594. — *Aspidistra lurida* (the Parlor Palm).—This is one of the best of room plants, flourishing under conditions which would kill most other plants, even standing a certain amount of gas in the air. It needs, however, constant care to keep its broad leaves clean

the surface-soil is really dry; then enough should be given, in a warm, to run through the pot, the cancer being emptied half an hour afterwards.—I. L. R.

4671. — *Window plants.*—Most of those mentioned may be preserved very well in any spare room to which more than a few degrees of frost gains entrance. Do not cut them down now—it is too late, but expose them freely to see and fresh air for a time, and they will be safe enough. Very little water will be required—in fact, the less the "Gardeniums" get the better, at least in very cold weather, Fuchsias must not get too dry, or the wood will shrivel and perish. Spiraeas are hardy, and will be all right if plunged in and covered with ash or a sheltered corner out-of-doors. The Hydrangeas also are nearly hardy and may be safely wintered in the frame.—B. C. R.

4656. — *Spring bulbs.*—The object of plunging pots of bulbs in ashes is a twofold one. In the first place, the weight of ashes over the bulbs prevents the roots lifting the bulbs out of the soil, which in the case of Hyacinths would certainly happen. Again, when the bulbs are plunged in ashes or Cocoa-nut-fibre, they are in a suitable position to make healthy roots without starting the tops, and this also in the case of forced bulbs is an advantage. A dark cupboard is not a bad place for bulbs where they cannot be plunged outside; but there should be no artificial heat, the cupboard should be cool.—E. H.

— For this purpose the ashes should be used just as they come from the grate, with only the large cinders sifted or picked out; never mind about the dust. The pots are to be plunged in the ashes, and then covered with the same to a depth of full 8 inches above the tops. Here the pots must remain, in a cool place, but protected from heavy rains, until they become full of roots and the bulbs begin to push into growth, which may be seen by examining a few now and then. If you put them in a warm and dry cupboard they will start into growth

The Moccasin-flower (*Cypripedium spectabile*), in the rock garden. (See page 444.)

when grown in a city, for no plant can do well when its pores are clogged with dirt. *Aspidistras* do not often need repotting, but when it becomes necessary it should be done in April, so as to give the slow-growing roots the summer in which to make their fresh start, and the best soil is a compost of peat, leaf-mould, and loam, in equal quantities, with enough silver sand to make the whole light. But these plants will grow in any ordinary potting-soil (not getting measure), with good drainage and proper watering. They do not require strong sunshine, and may stand for some time away from a window without being injured. Water should only be given to all room plants when needed—i. e., when

before any roots are formed, and the flowers will come to nothing. These are hardy subjects, and must be kept in a cool dark place during the early stages, and brought into heat (if required) after the growth has commenced.—B. C. R.

4670. — *Plants for next season's blooming.*—You had better buy good plants of the various things mentioned, and they are not expensive; otherwise you will not get good specimens for blooming next year. You may plant any or all of them now, except the Pentstemon, which should not be put out until the spring; as they are not very hardy, getting much cut up in severe winters.—C. T.

OUTDOOR PLANTS.

A GARDEN IN VENICE.

PRIVATE gardens of any extent are almost unknown in this beautiful city of waters, and though some of the larger houses have attached to them a court-like enclosure where grow a few Oleanders and Cypruses, yet such small spaces do not satisfy the English craving for a real garden. An English resident, Mr. F. Edan, living in one of the fine old palaces on the Grand Canal, had the happy idea of buying a piece of ground of some acres on one of the adjacent islands. It was already well furnished with a luxuriant

parts. A good Grass lawn has also been made, and an artesian well been sunk; this is a most important improvement, as it yields an abundant supply of good fresh water, whereas formerly water had to be brought in large-loads from the mainland.

PERGOLAS, OR CREEPER-COVERED WALKS.

In Italy and other parts of the sunny south one often sees in gardens the pergola, as the creeper-clad arbor or walk is called, and which generally serves the two-fold purpose of supporting the Grape-Vine and affording pleasant coolness

tissima, Periploca græca, Clematises, Honey-suckles, Bine Passion-flowers, Bignonia radicans, and B. grandiflora, Scarlet Trumpet-flower (Lonicera sempervirens), and other beautiful climbers—which formed the most delightful retreats in flower-time, and were always cool and shady in the hot summer season. But these seldom occur outside the rich gardens of the great villas, and usually near humbler dwellings the pergola is a simple structure made for the purpose of supporting the Grape-Vine. The

PERGOLAS, like the stately fountains, are in Italy quite appropriate to the country and the climate, but they are rarely necessities in our English climate, though adaptations of the pergola if simple and unpretentious would add to the delights of many an English garden, even if we seldom feel the want of a shady bower at midsummer. A creeper-clad trellis spanning a frequented walk is a most desirable feature in a garden, as it is a contrast to the open breezy parts, and not only this, it serves as a suitable place for growing the multitude of beautiful hardy climbers we have now at our command, and which can only be seen when rambling over trees, trellises, or along the tops of walls. Some little consideration is required in deciding upon the most appropriate place for a covered way. It should lead to somewhere and over a frequented walk, and should not be erected where any line of view would be interrupted, or too prominently in view, that it is always in sight from the house, and if it can be placed so that a stranger would come upon it unawares so much the better. The breadth, height, and length are points for individual taste and circumstances to dispose of, but if flowering creepers are desired to cover it, it must not be placed under or near the shade of big trees, especially such as Elm, whose hungry roots would travel a long way to feed upon the good soil that the creepers must be planted in. The form of the structure must also be governed by circumstances and individual taste. A simple structure is the best; the supports should be Oak-tree stems, about 3 inches in diameter with the bark on, let into the ground about 2 feet; if on a bed of concrete the better. The posts must be connected and firmly secured to each other by long pieces of similar size and running along the sides, while the top may be formed of small pieces fixed transversely across the top. This will make a more massive and firm structure, and the simpler it is kept the better it will look. On no account let the rustic wood carpenter begin to adorn it with his fantastic branches, which he is usually so fond of doing. If a more polished structure is desired, the supports may be round, square, or hexagonal, and the roof made of diagonal trellis-work of Oak or Teak with the meshes about 3 inches across, and instead of being flat it may be gently curved. Such a structure would be appropriate close to the house where it could be looked down upon. On a close trellis the creepers do not festoon themselves beneath it or flower so freely as in the open cross-piece trellis. Some, no doubt, may like a variety of

CREEPERS on a trellis, but I like to see it covered with one or two, such, for instance, as Laburnum and Wistaria, which flower together and look beautiful in June, and never give a dense shade. Climbing Roses would cover another, Honeysuckles another, Jackman's Clematis and C. montana a third, and so on. In warm parts one could have the pergola covered with the lovely white Solanum jasminoides mixed with Passiflora scerulea or Tecoma grandiflora. The various Honeysuckles, especially the Scarlet Lonicera sempervirens and L. brachypoda, would go with the Sweet Jasmine (J. officinale), and up the pillars may be trained the yellow winter-flowering J. undiflorum, Forsythia suspensa, Cydonia japonica, Escalonia macrantha, Myrtle, Garrya elliptica, Chimonanthus fragrans, Berberis stenophylla, and others, though not strictly climbers, would drape the supports of a pergola. There is such a number of climbers to choose from that the difficulty is to make the best selection. Care should be taken not to choose any doubtfully hardy plant, for it is annoying to find that after a severe winter a blank space has to be recovered.

W. GOLDRING.

House in a garden at Palazzo Barbarigo, Venice. Engraved from a photograph sent by Mrs. Eden.

growth of Vines, Figs, Mulberry and Cherry-trees; but much had to be done, and now, after some years of judicious planting and expenditure, it is a beautiful and delightful garden, and an unfailing source of interest and enjoyment to its owners. The best flowers have been introduced from English and other gardens, and nearly all take kindly to the soil, which is formed of the rich, reclaimed mud of the lagoons. White Lilies are a special feature, and grow in great masses beside the walk under a pergola of Vines, as shown in the illustration (p. 447). Roses are equally luxuriant, and are freely trained on the high wall of a building that bounds the garden on one side, and on the little house (as well as in the engraving as well as in many other

during the summer heat. As a rule, these pergolas are rude trellis-work structures of wood, sometimes supported by stone where this is at hand, but more often the supports are of rough tree-stems, as shown in the cut on p. 447, which illustrates how a thickly-covered pergola is used to give the necessary shade to the Madonna Lily (Lilium candidum) in a climate where full exposure to an almost tropical sun would be detrimental to it. In the gardens in the neighbourhood of Rome, Naples, and Florence I have seen some beautiful examples of the pergola—stately structures, the supports of which were massive columns of stone covered and festooned in a beautiful way, with such as Bankian Roses, Wistaria, Pergolas, and

1893. Making a tennis-lawn.—The lawn selected for the court should not be less than 50 feet long and 40 feet wide. When the

court is smaller it is of little use, as there is considerable wear and tear, especially if the Grass is much played upon. The site should be as level as possible, as if there should be only 6 inches difference between the levels of the top and bottom ends of the plot, it will not be necessary to make a true level, but only to smooth the ground by forking it up and raking it. Then if a tight line be drawn from corner to corner, any slight irregularities of surface will be at once seen, and must be then corrected. If, however, the plot of ground be very uneven, proceed in this way: First find the centre of the plot, and then drive in a very stout stump of wood, the top of the peg being on a level with the ground. This is the key to the whole work. Then drive in other pegs to the corners of the lower end of the plot, the top of each peg to be on the same level as the centre or main peg. Now from the centre dig out a drift to each of the top or higher corners of the lawn, and put pegs in every 6 feet or so, preserving the same level all the while. This spare soil will be whashed to the lower level, and spread over the ground to the tops of the pegs, and then well

is past it is better to wait till spring, and during winter get the land thoroughly cultivated and, if necessary, manured. To get a good turf quickly sow thick. I should sow a peck and a-half of good seeds. Ashes will hardly be necessary on a gravelly soil. Ashes are useful on damp soils to keep down worms, but on dry soils I should not use them.—E. H.

4579. — **A new garden.**—There is no need to destroy the worms; but if they become a nuisance there is nothing better than a good dressing of quicklime dug in now. I should, if it is thought necessary, put on a dressing of manure after the lime has been forked in, and if the surface of the soil is rough, and the manure short—as it ought to be—most of it will disappear during the winter. Lime is excellent for fruit-trees—in wet soils especially so.—J. D. E.

— The best way of getting rid of some of the worms in your garden is to keep three or four fowls in a movable run, changing the run every day, stirring up the soil previously to moving the run. Do not feed the fowls for some time after they have been given the

vigorous. The month of November is a good time to apply manure to fruit-trees. If the trees last year made sufficient growth it is a good plan to mulch the surface for 2 feet around the stem of hush fruits with partly decayed manure after the fruit is set. In the case of Apples or other large fruit the manure should extend fully 3 feet from the stem. This mulching prevents the evaporation of moisture and keeps the roots cool during hot weather, thus inducing them to multiply, which is what is required. If slugs are troublesome, or the ground heavy and retentive, a dressing of lime on the surface will be good.—S. P.

4576. — **Carnations in a smoky district.**—The arrangement described will answer perfectly as far as the Carnations are concerned. There must, however, be ventilators in the roof as well, by means of which to admit air when the weather is too cold or rough to admit of the slides being opened. Where there is much smoke about, lifting ventilators, hinged at the top, are superior to such as slide open, as they do not allow of the entrance of smuts, like the latter. Roses are very "kittle-cattle" in a

OUR READERS' ILLUSTRATIONS: Perigoa with White Lilies underneath at Palazzo Farnesio, Venice. Engraved for GARDENING ILLUSTRATED from a photograph sent by Mrs. Eden. (See page 116.)

rammed or trodden down. Now fork up the hard ground lightly on what was formerly the higher level, and spread part on the lower half. Then well tread it all over, and smooth with a straight edge. Drains are generally unnecessary, but where they are absolutely required, and the soil is stiff clay, put them in not deeper than 6 inches. Above the pipes put a few inches of Gorse or Heather, filling up with fine soil to the level of the surrounding ground. Procure the best turf obtainable in the district. Do not trust to grow seed. Well roll or beat the turf as soon as it has taken root, not before, as is often done. The ground surrounding the lawn must be brought down to as gentle a slope as possible, and must also be turfed, being treated in the same way as the lawn. As to coat, every thing depends upon the nature of the soil and weather experienced during the progress of the work.—G. T.

— It is rather late for sowing Grass seeds now. If it was mild up to Christmas they would be all right, but even then the weeds might get a start. I always think Grass seeds do best if sown when the conditions are favorable for immediate growth, and after September

change of position, or they will not take the trouble to search for food. I would, however, prefer to have a garden with plenty of worms in the soil than without them. If there are no worms, you may be sure the ground is too poor to induce them to stay. Autumn is the best time to use manure in your case.—J. C. C.

— The presence of worms in the soil is not detrimental to the garden at all. For vegetables, directly any crop is cleared the soil should be trenched 18 inches deep, if not already done, taking care to keep the surface soil on the top. The advantage of deep digging has had abundant opportunities this year of manifesting the wisdom of the practice. Soil deeply moved retains the moisture much better than that which is shallow. The advantage of digging the ground now is that of exposing the surface to the weather so much longer. If manure is available, as it should be for the main of the vegetable crops, especially for all of the Brassica tribe, it ought to be buried now, not more than 1 foot deep. If the fruit-trees did not make much new growth during the past season, liquid manure should be lightly forked in among the roots to induce them to become more

smoky district, and should be undertaken with caution. Try a Gloire de Dijon at first—under glass, of course—and if that succeeds you may proceed to others.—B. C. R.

— Grow the plants in 3-inch pots, two plants in a pot, and if the plants are well cared for they will do well and throw plenty of blossoms and make plenty of grass.—E. H.

A border of Narcissus minor.—As this is the season to plant Daffodils, a note may be made of this little dwarf Daffodil for edgings, as when the bulbs are planted moderately close together the flowers have a pretty effect in the spring. I saw last spring a border, the margin of which had been planted with this Daffodil, and the effect was very pretty, the border itself filled with a variety of bulbs, amongst which annuals were sown to maintain a display of flowers in the summer months. Chionodoxas and Snowdrops also formed part of the edging. All these little dwarf kinds are very pleasing, also on a sunny bank where the Saxifrage and Sedums are at home, the Daffodil flowers appearing above the dense green mat of vegetation. They are of exquisite shape, small, and a counterpart of those of the English wilding.—C. T.

INDOOR PLANTS.

4673.—**Plants for conservatory.**—You may have in your conservatory a variety of plants, and we should add the white and crimson *Lapagerias* to your list, and the white *Plumbago*, which goes exceedingly well with the blue-flowered type. Ferns you can have in abundance, filling hanging-baskets with such kinds as *Nephrolepis exaltata*, whilst *Cyclamens*, Chinese *Primulas*, *Chorozemas*, *Ericas*, particularly *E. hyemalis*, *Froesias*, *Camallias*, *Azaleas*, and a host of hulious things, as *Hyacinths* and *Tulips*, may be enumerated. Do not have too many creepers overhead, as they keep out the light. Zonal *Pelargoniums* would bloom well through the winter, and also you could have such plants as *Pernettyes* in pots, which are bright with variously-coloured berries through the winter months. *Cytisus rooseanus* is a good plant; but this will be a good selection to commence with.—C. T.

4642.—**Flowers for Christmas church decoration.**—One of the most useful flowers of a hardy nature that can be used for church decoration at Christmas is the Christmas Rose (*Helleborus uiger*), and it is largely employed for the purpose. The plants respond very readily to gentle heat, and a healthy clump will provide a large quantity of bloom which, owing to the protection of glass, does not get sullied by the weather. If the clumps are to be lifted, they may be put—when the buds are getting advanced—into baskets, which should be filled with Cocoa-nut-fibre or similar material, and placed in a warm-house. I have prepared many baskets in this way; but the clumps must be well established. After the flowers are over, stand the plants out under the shelter of a wall, protecting slightly, and when the weather is favourable they may be planted out in the position from whence they came; not, however, to be disturbed again for two years. Forcing each year is too much for them. They must have a season in which to recover. I have also out many flowers from plants in the open, and merely protected with a hand-light, put on when the buds are fairly well developed. But, of course, if you require quantity of bloom, lifting the clumps and giving them a warm temperature is the plan to adopt. If you have a warm greenhouse there are many white flowers available at Christmas, such as *Chrysanthemums*, *Bonvardias*, Chinese *Primulas*, to mention only a few; but in recent numbers of *GARDENING* the subject has been dealt with.—C. T.

Very much depends upon means at disposal. The Christmas Rose, if strong roots are potted now, will come on in a cool-house. White Roman *Hyacinths* and *Deutsche Perle Azaleas* may easily be brought on in a warm-house. There will be plenty of late White *Chrysanthemums* at Christmas. *Eucharis Lillies* are charming. White *Ahutilons* (*Boule de Neige*) planted out in the greenhouse will yield plenty of blossoms; but the most effective flowers are *Eucharis Lillies*, White *Chrysanthemums*, Christmas Roses, and White *Azaleas*. None of these things can be improvised; if they are not already in stock they must be purchased.—E. H.

4646.—**A frame pit.**—I like your idea of a frame pit, as they are more serviceable than the ordinary wood frame. The most useful structure ever I made was a span-roof pit, built on the ground level, with the ends running north and south. The sides and ends were of 4½-inch brickwork to a height of 2 feet, and the interior width was 5 feet. To this was fixed a wood frame in span form, with lights 2 feet 9 inches wide, and movable. The floor was paved with bricks, and the angle at each end was filled up with glass. In such a structure many plants can be kept through the winter with ordinary care, because the height and width admits of external covering being used without difficulty; and I see no objection to an oil-lamp being used in time of severe frost. In such a pit Cucumbers and Melons can be grown in summer, and also Tomatoes, and every attention can be easily given the plants. Do not be tempted to sink your pit below the ground level, or you will lose more plants in winter through damp than from frost.—J. C. C.

4678.—**A small cold-house.**—It would be better if you devoted such a small house to one

thing, either Vines or Tomatoes, but if you decide on growing both you had better have half the house with Vines and the other half Tomatoes. Two Vines—one Black Hamburg and one Foster's Seedling (white)—will be enough; let each have a single rod trained up from the east side and down the other. The border should be outside, and the Vines nearest the end should be 2 feet from it, and the other Vines 4 feet from the first. It is not absolutely necessary to heat the house for the subjects you intend to cultivate, but you will find it much more serviceable to do so, and it does not cost much to build a flue. The beginning of February is a good time to plant the Vines. It is better, however, to get them home early in the winter, and to put them down to a point that will reach inside the house when they are planted. You will have to fix wires inside the roof and 1 foot from it for the purpose of training the Vines and Tomatoes to it.—J. C. C.

4679.—**Ivy-leaved "Geranium."**—Madame Crouse is one of the best of the Ivy-leaved section for such a purpose as required by "Wicklow," being a vigorous-growing and a frax-flowering kind as well. *Souvenir de Charles Turner*, deep-pink, feathered-maroon on upper petals, is also a good variety. The foliage is massive and flower trusses of huge size. The individual pipes are 2 inches in diameter. If the plants can be grown on in a greenhouse early in the year, so as to be of good size when planted out in the boxes, some valuable time will be saved, and the sides of the porch will be covered much quicker than though planting was deferred until the end of May.—S. P.

They will do very well in boxes. There is nothing better than *Mme. Crouse*. *Joan of Arc* is a good white variety, very free, but will not grow so fast as the first named. I have grown these two largely, and can recommend them.—E. H.

Yes; such boxes as you describe will accommodate one or even two plants of the above species comfortably. These plants do not require so much root-room as many others.—B. C. R.

4647.—**Oil-stoves for greenhouses.**—Seeing that every maker of these stoves claims his as the best, I do not see how anyone is to tell you which is the best unless they had tried them all. I have tried *Teape and Sons*, also *Rippingille's*, and I found them both good. But as regards the cost of oil I think that *Teape's* burns the least. Both, however, are costly, and for a house of the dimensions of yours the cost would not be less than 6d. for twenty-four hours in severe weather. In an average of winters there would not be more than four weeks of such weather, so that for the remaining four months the cost of oil would be at least one-third less. You will please understand that these calculations are made on the assumption that you would only light the stoves to keep out frost.—J. C. C.

4677.—**Heating a large greenhouse.**—I fear oil-lamps or stoves will be of little avail in heating a structure of these dimensions; the height adds considerably to the difficulty. On the whole, I should advise you to have a good flue put in. This would come much less expensive than hot-water pipes and a boiler, and would afford a nice, quiet, steady warmth with but little attention, especially if constructed with the deep square furnace I have so often recommended. I should advise a double flue—the lower part of brickwork, with a return of 9-inch earthenware socket pipes along the top.—B. C. R.

4641.—**Lemon-scented Verbenas.**—The propagation of this plant is, like a good many other things, very easy when you know how to do it, or get the knack of managing the cuttings. The best time to take the cuttings is in the spring, when the young side-shoots on old plants are from 1½ inches to 2 inches in length. Take them off with a "heel," using a sharp knife, trim off the lower leaves, and insert them at once in pots (the 6-inch size is a good one) or boxes of light sandy soil, such as a mixture of fine loam, sand, and leaf-mould, Cocoa-nut-fibre, or peat, in about equal parts, with a surfacing of pure fine sand, and extra free drainage. The best place for the pots is plunged in a gentle hot-bed at 60 degs. to 70 degs.—more than this is injurious—and if kept fairly moist, close, and carefully shaded from sun, few of the cuttings will fail to root and grow. I have also rooted them capitally in a bed of drying (drying) small propagating pit, built over the pipes in a

warm greenhouse, keeping them rather closely covered with glass and shaded, and also in April or May in an ordinary box of well-drained sandy soil, deep enough to allow of a sheet of glass being laid over them. Drought, excessive heat and sunshine are the chief obstacles to success; if the outtings once flag badly it is all over with them.—B. C. R.

The present is a bad time to strike cuttings of this plant; wait until new growth is being made in spring. Take off the young shoots when 3 inches long, preserving a small portion of the old wood, commonly known as an heel. Remove the lower leaves an inch or so up the stem. Dibble the cuttings around the edge of a 3-inch pot, nearly filled, firmly with sandy soil, sprinkling a little sand on the top, a little of which is carried down to the bottom of the hole with the dibber when making a hole to receive the outtings, as they make roots more quickly in sand than soil. Make the outtings quite firm at the base, give a gentle watering to settle the soil and sand about the outtings. Place the pot under a hand-light in a Cucumber-house or in a gentle hot-bed where the heat is not too strong; shade from bright sun, and in three weeks' time every cutting ought to be rooted.—S. P.

Cuttings of pipe wood will strike very well in early spring in gentle heat in light, sandy soil.—E. H.

4675.—**Heating a greenhouse.**—An ordinary lamp-stove with a 4-inch wick might suffice to just exclude frost, unless very severe; but I should much prefer one of the "radiator" stoves, as being at once more effective, more economical in fuel, and affording a more healthy atmosphere. Roof ventilation only is required during the winter, and two small lights of say 2 feet by 18 inches in the top of roof would be ample.—B. C. R.

4653.—**A lean-to greenhouse.**—I am afraid you will find it a rather expensive matter to heat a house of this size with gas. The height makes a great deal of difference, as the heat naturally rises to the top. You will want at least three rows, equalling 90 feet, of 4-inch piping, and it will need a large and powerful boiler to heat this amount. A good independent slow-combustion boiler to burn coke would be far more economical in fuel, and require little more attention. *Teape's* Champion is about the best gas-boiler I am acquainted with.—B. C. R.

4650.—**Purchasing a greenhouse.**—You will probably find it at once cheaper in the end and more satisfactory to purchase a ready-made house, or, at least, the wood-work already fitted and marked to go together. You do not say whether you intend to build up brickwork, or go in for a "tenant's fixture." Unless the man is used to this kind of work he is sure to make mistakes, and these may prove costly in the end; but do not obtain one of the very cheap structures advertised, which are dear at any price. The best kind of heating apparatus for a small house of this description is undoubtedly two or three rows of 3-inch or 4-inch hot-water piping, heated by a small independent slow-combustion boiler. Gas or oil may be employed as the heating medium for small structures of up to about 150 square feet of area, and these require less attention than a small fire, but unless of a first-class make, you will find them come rather expensive in fuel.—B. C. R.

4598.—**A greenhouse during frost.**—I have tried a good many things, but I found frigi-dome (a woollen fabric) the most satisfactory, though mats sewn together and tacked on the roller need for blinds in summer did very well. Any covering which can be rolled down at night and up in the morning is the most useful. Light straw mats would, I have no doubt, answer well. Coverings which do not touch the glass are the most effective. Some years ago I carried out a series of experiments to test this matter, and I found in every case where there was a couple of inches of confined air between the covers and the glass the temperature inside was higher. This is what might be expected under any circumstances. I am writing from memory, but I think the difference in favour of the covering which did not touch the glass was from 4 degs. to 5 degs. Blinds used for shading in summer are very useful to roll down on cold nights if made secure from wind disturbance.—E. H.

ROSES.

ROSE HON. EDITH GIFFORD.

HON. EDITH GIFFORD is well deserving of the honour as the best of all the White Teas, not so absolutely colourless as Niphetos, but in habit, freedom, form, and constancy presenting an irresistible claim to the position, and requiring only to be known in order to become one of the most universally popular of all the Tea-scented Roses. That is to say, of the non-climbing section, for Edith, as, with excusable familiarity, rosarians habitually call their favourite, though "most divinely fair," rather than "divinely tall," is somewhat short of stature, yet no way lacking grace, pale almost to whiteness but for the soft fresh tinge deepening sometimes into a rosy-blush, neither coy nor capricious, but gracious always and constant, the full round form a model from every point of view. This charming Rose is said to have been raised from Perle des Jardins and Madame

such as Innocente Pirola, &c., is in the great substance of its petals, which are not easily stuck together by wet, so that the flowers upon fair even in cool and damp weather. This is the best White Tea for making an effective group in the garden, owing to its erect habit of growth, its extreme freedom of bloom, and its exceptional constancy, so it must be admitted that such a Rose has every claim to rank among the very best of even the most exquisite of all—namely, the Tea-scented Rose. It is difficult to dissociate the name of their raiser from the names of some of the finest (including Comtesse de Nadaillac and Catherine Mermet) of all the Teas; but it may fairly be said that Guillot would occupy a higher position than a good many other raisers not unknown to fame, even if he had raised nothing else and his reputation depended solely upon the Hon. Edith Gifford.

4635. — Rose Gloire Lyonnaise. — "Miscwber's" description of the behaviour of

PEGGING DOWN ROSES.

"J. O. C." does not seem quite decided in his mind as to the wisdom of pegging down the long shoots of vigorous growing Roses. There are a few unsatisfactory ones which droop their flowers, and it is apparently on this point that "J. O. C." wants some assurance. At the outset let me say that Gloire Lyonnaise is one of the very best of all Roses for pegging down, and under no other method of treatment have I obtained such a large quantity of blooms from each plant. It is a most characteristic Rose, and not another that I know grows like it. I have a large group which was planted when the kind first came out in heavy, deeply trenched loam. No manure was given then and none since, for the plants never fail to throw up a forest of shoots each year, these varying from 5 feet to 7 feet in height. They are straight as darts and stand quite upright. On the tops of these shoots lately have been some fine flowers, but it is not a profuse autumn-blooming kind like the true Teas. But to prune those long shoots back would be wanton sacrifice of flowers. When pegged down almost their whole length the weak tip of the shoot is taken off. Every eye throws a flower on a shoot about 9 inches or 1 foot long, standing up boldly erect as if the habit of the kind. I have never seen a drooping flower on this Rose, and must therefore take exception to its fitness for pillars, upon which I like to see drooping flowers. Gloire de Margottin is a good type of pillar Rose, brilliant in colour, and drooping in habit. I tried this pegged down, and it was a failure. But the very best Rose for pegging down I have ever tried is Mme. Gabrielle Luizet. So treated, it is a marvel of free blooming. On a group of six plants I once had over 300 buds and blooms in varied stages of expansion in one day. It, too, stands quite erect. Ulrich Bruner did very well also, and so did the Dijon Teas, including the good old Gloire de Dijon itself. I am bound to say, however, that Gloire de Lyonnaise and Mme. Gabrielle Luizet are two of the very best, and, if equalled, they cannot be surpassed for this form of culture. A. H.

Rose "Hon. Edith Gifford."

Faloot, and in habit, wood, and foliage bears considerable family likeness to Levet's beautiful seedling; for the growth is erect and sturdy, the stems deep red, and the foliage dark coloured and very handsome, forming an admirable contrast to the brilliant purity of the boldly-displayed white flowers. These are produced in such abundance from early summer until late autumn that it might be expected that many would be ill-shaped; but, as a matter of fact, hardly a flower is ever lacking in form, whether in bud, half open, or fully developed, and the Hon. Edith Gifford is as constant among the Teas as in A. K. Williams among Hybrid Perpetuals. A variety to which the Rose under notice has often been compared is Devonienne, and it is not improbable that this in many places will be superseded by the Hon. Edith Gifford, which is more vigorous, less tender, infinitely more free-flowering, and whose flowers, even when in full bloom, never assume a flat, pancake shape. Another point in which the Hon. Edith Gifford is superior to other White Teas,

this grand H. Tea when pegged down suggests to me that he does not peg down until after growth has commenced. When pegged down at pruning-time I have never found Gloire Lyonnaise behave as he describes. It certainly does not bloom with so much freedom when grown in an upright position, and when pegged down properly I have never noticed the young bloom growths more horizontal than other strong growers under the same treatment. —P. U.

4638 — Rosea in an unheated greenhouse. — Certainly a Rose, such as a Maréchal Niel or Climbing Niphetos (the common dwarf variety of the latter would be useless), would thrive in such a position—at least, if kept free from aphides and other insects. I should not, however, train a single stem immediately under the ridge, but take up two, and train them one on each side, 9 to 12 inches from it. —B. C. R.

Yes, a Maréchal Niel Rose would do trained in the way you suggest. The only objection that can be raised against the arrangement is that when the growth of this kind is trained near to the ventilators it is very subject to mildew. —J. C. C.

4636. — Treatment of Begonias. — Possibly you have kept the plants too wet, as this, or the reverse, would cause the flowers to drop off. But you must remember that the flowers are naturally not very long-lasting, and, especially if the plants are handled at all carelessly, soon fall. Your treatment appears to have been all right, and I do not know why you complain, as you say the plants have flowered well. They will not keep gay throughout the winter, and if not already showing signs of going to rest, they will soon do so. When you observe the leaves beginning to turn yellow, keep the plants on the dry side, but withhold water quite gradually, until you can relinquish it altogether. Sudden stoppage in the supplies is most harmful. When the foliage has quite died down, you may store away the bulbs for the winter; keep them in the pots, and place under the stage of the greenhouse, or similar position, where they will be safe from frost and dry. —C. T.

4624 — Spiraea japonica. — Unless your crowns have done exceptionally well since being parted and planted out last summer, they will not be sufficiently strong to force again this season. Owing to the dry weather, they are hardly likely to be strong enough, and I would strongly advise your leaving them where they are until next autumn, when they will have developed into good roots. It will aid them very much, and at the time afford a little useful protection if you mulch them with rough stable litter during the winter. —P. U.

— The second growth and bloom will not do the plants any good, but if you leave them alone till December, then pot and place them in a cool frame or pit, and bring them on a gentle heat early in March, with plenty of water and a little stimulant, they ought to force fairly well. —B. C. R.

4644 — Freesias. — When well grown, Freesias should not be long in the leaf and droop over. This is probably the result of growing them under the Vines. Freesias, to have them sturdy, should be grown in the full light, in a freely ventilated house, as near the glass as possible. —E. H.

4662 — Sawdust as manure. — Pure sawdust is about the worst stuff that can be put on a garden, as it secures the soil and produces no end of fungi; but when saturated with urine, &c., this fault disappears, and it may be safely employed for almost any crop. Add a very little lime only, just to keep all sweet. —B. C. R.

THE KITCHEN GARDEN.

POTATOES OF GOOD QUALITY.

It is well known that the soil in which Potatoes are grown has a good deal of influence on the quality, but, notwithstanding this, I can name four sorts that will in the majority of cases prove valuable. These are Myatt's Ashleaf, Covent Garden Perfection, Puritan, and Magnum Bonum. In this part of the west of England Rocks are largely grown both by cottagers and farmers. Consumers do not mind

Potato "Rosette."

having a deep-eyed Potato when the quality is good, and I have not the least doubt but that Rocks will remain a favourite late-keeping Potato for many years to come. Quality is everything in a Potato, while appearance counts for nothing. It is rather singular that the Rocks should retain such a hold of public favour while so many much handsomer sorts have been introduced only to quietly drop out of cultivation. It, however, shows that the consumer soon learns to discriminate between Potatoes of good and bad quality. Covent Garden Perfection has often been referred to in very favourable terms, but not a word too much has been said in its favour. I have grown it ever since the first year it was introduced, and have seen it growing in many different kinds of soil, but it has always retained its character of being an excellent cropper and the table quality all that could be desired. It is a second Early, being ready for lifting generally about the middle of August, while the tubers will keep sound and retain their flavour until the end of the following March. Puritan is, perhaps, better in light land than heavy. It, however, adapts itself to a variety of soils better than some other sorts. I do not remember having at any time seen any allusion made to the loss in weight that Potatoes are subject to when they are stored in heaps for several months. I have, however, good reasons for knowing that it is a fact that they do so, and to a greater extent than I was prepared for, and the larger the tubers are the more they appear to lose in weight. Two years ago I weighed several sacks of Champion and Magnum Bonum as they were taken to the store, and weighed them when taken out four months later. The loss of weight during that time was not less than 10 lb. on every hundredweight. Two excellent types of Potatoes are here figured—Rosette and Schoolmaster. J.

PLANTING EARLY CABBAGES.

EARLY Spring Cabbages are always greatly appreciated, as they come in at a time when one has had to rely on root crops for a good deal of the vegetable supply, and to have them as early as possible should be the aim of all kitchen gardeners. There is generally plenty of land vacant at this time of year where Onions or Potatoes have been cleared off, and the first thing is to put a good dressing of manure on the land and dig it in deeply, for good crisp Cabbages cannot be grown on poor soil; then set your lines out about 2 feet apart, and put the plants in about the same distance in the row if they are intended to stand to get fully grown or are of fairly large kind; but if they are to be

in the row for any of the small garden Cabbages that are never better than when they are only three parts grown, according to the market gardener's standard, and most people find it best to clear off the Cabbage-bed early enough to crop the land with Potatoes. There are many good sorts, but few to surpass Wheeler's Imperial and Early Rainham. If the soil is dry, water freely, and they will soon get rooted and take care of themselves, and as soon as they fairly start into growth stir the soil amongst them with a hoe, and before the winter sets in draw a little soil up to protect the stems from frost. J. GROOM.

4668.—**Mushrooms and Rhubarb in a shed.**—The dimensions of your shed is right enough for the purpose you intend it for; but you cannot force Mushrooms and Rhubarb at Christmas without having it heated. I should prefer the Rhubarb on the floor and the Mushrooms beds on the shelf. A small portable stove will no doubt be the simplest way of heating, but hot-water pipes will be better. In either case you will find the air of the shed get dry if moisture in some way is not given. Probably damping the floor will do.—J. C. C.

4695.—**Making leaf-mould.**—A very good way to make leaf-mould is to use leaves for a hot-bed for early Potatoes, or some other crop. Early Lettuces would do well on a bed of leaves. This is making some use of the warmth generated

Potato "Schoolmaster."

by fermentation, and at the end of the year the bed should be turned over and intermixed. If there are not leaves enough to make a small hot-bed, place them in a heap in some out-of-the-way corner, spread a little soil over them to keep them from blowing about, and leave them to decay.—E. H.

4655.—**Treatment of a Bermuda Lily.**—Better start fresh with a new bulb. The flowering exhausted it, and it is not likely to do so well again. The bulbs are cheap now.—E. H.

4572.—**A new lawn.**—There is no necessity to put either manure or lime on the Grass of a newly-laid lawn; certainly not at this season. The manure, if any, ought to have been dug into the ground before the turf was laid, and a sprinkling of lime also would have been probably beneficial. If the Grass is at all weak or thin you may give a light top-dressing of well-decayed leaf-mould in the spring, just before it begins to grow again; but it is neither necessary nor desirable to induce the Grass on a lawn to grow too strongly.—B. C. R.

4643.—**Colours of Violets.**—Marie Louise, rich mauve, lavender blue, with a white eye; the flowers are large. This variety is perhaps the best of all the double-flowered kinds for frame culture. Comte de Brazza, white, of the Neapolitan type, good for spring flowering. Mme. Millet, violet-purple, shaded with carmine, very free and distinct. De Parme, pale lavender-purple, a little later in flowering than Marie Louise; a capital sort also.—S. P.

4686.—**A boarded fence.**—Red Currants would be a success on the north side of a wooden fence. There would be scarcely height enough for Plum or Morella Cherries, otherwise they would succeed. The brick wall would do well for dessert Pears to be trained horizontally. Plant Pears, Apples, Plums, and Cherries 15 feet apart. Red Currants 4 feet to 6 feet apart. Good kinds are Pears: Marie Louise, Louise Bonne de Jersey, Pitmaston Duchess, and Doyenné du Comice. Apples: Cox's Orange Pippin, Blenheim Orange, Echlinville, Allerton, Peasgood's Nonsuch, and King of Pippins; and Plums: Green Gage, Victoria, Pond's Seedling and Prince Englebert.—E. H.

—Cordon Pears planted 2 feet apart would succeed capitally on the south side of the boards, and so would Plums. Those latter are generally trained fan shaped; a space of ten feet apart is not too much for the latter. Of Pears the following varieties are good: Jargonelle, William's Bon Chrétien, Pitmaston Duchess, Marie Louise, Louise Bonne de Jersey, Winter Nellis, Passé Crassane, Duchesse d'Angoulême, Clapp's Favourite, General Tolleben, and Josephine Malines. The ripening season of those named extends from August until March. Green Gage, Victoria, Jefferson, Kirke's, and Prince of Wales are fine relishing sorts of Plums. On the north side of the fence Morella Cherries, Red and White Currants would succeed. On the western exposure sweet Cherries would succeed. These are best trained fan shape. A space of 12 feet would not be too much from tree

to tree. Governor Wood, May Duke, White Heart, Bigearrean Napoleon, and Elton are deserving kinds to plant. If the wall gets most of the afternoon sun it might be advisable to plant a couple of fan-trained Peach-trees. Helo's Early and Dymond are reliable; the former is an early sort and the latter a mid-season kind. Early in November is a good time to plant the tree. The soil should be deeply dug at once, so that it will have some time for the soil to settle down to near its natural position before planting.—S. P.

FRUIT.

KEEPING GRAPES.

IN reply to "G." and others, a room over a stove-hole is anything but a good position for storing Grapes in, especially if the temperature stands so high as 60 degs. From 45 degs to 50 degs. has been repeatedly proved to be the most the case, and a room that keeps near these figures without either the assistance of

Ferrière mode of fixing the bottles.

much fire-heat or the admittance of air is most desirable. The best place I have yet found for keeping Grapes is in a spare bedroom in a large old house. This is on the north side, has thick hollow walls, and is duly ceiled. There is a fireplace in it, but this is only used during the prevalence of very severe weather, being blocked up at all other times. There is a tight-fitting shutter to the window, and this is seldom opened, while the door is also kept locked. It will be found that Grapes in still warmer houses or rooms are constantly cool, and which can be most surely tested by placing a berry against the cheek, and in the comparatively low temperature of a fruit-room they are still colder. If a room is ventilated freely directly after a change from very cold to quite warm weather, the warm air quickly condenses on the cold walls, the moisture trickling down in streams, and we are told that this is simply the frost coming out of the walls. Much the same thing is liable to happen if warm air from the outside, and which is naturally highly charged with moisture, comes into contact with the Grapes, and once the skins have been damaged in that way, decay of the berries is inevitable and rapid. That is why Grapes keep so much better in a cool, properly constructed room than in ainery where much greater fluctuations of temperature and free ventilation at times are unavoidable. It is surprising what a great number of bunches may be hung in a small room, a series of simple racks formed as to support half-pint bottles in a sloping direction being all that is necessary on each side of the room. Mr. Robinson, in his work on the "Parks and Gardens of Paris," first drew attention to the simplicity and effectiveness of this plan of keeping Grapes, and the simple woodcuts here given will do more towards instructing "G." than any number of paragraphs from my pen. A bedroom not being available, then ought "G." and others who are anxious to keep a large quantity of Grapes till the spring, or, say, up to May, to construct a building specially for the purpose. In some instances it might be possible to convert a lean-to shed on the north side of a wall into a Grape-room, a wooden floor being formed, the walls thatched, and the roof either ceiled inside or thatched on the outside. If necessary a room could be built against a north wall preferably as being the coolest site and least affected by fluctuations of temperature, the side being either a wall of hollow brick or stone, or of wooden posts and match-boarding, a heavy thatch of either straw, Reeds, or Heath being necessary in this case. The roof should be either slated and ceiled, or, better still, slated and thatched. What light is needed at different times can best be admitted by either a hinged top light or from one end, this being covered up, as a rule. A single hot-water pipe carried round the room might be serviceable at times for the purpose of either expelling damp or for preventing very low temperatures through the opening in the roof. "G." can easily estimate what length his room should be, the height being regulated according to the wall against which it is to be constructed, and the length by the number of rail the room

will hold and the average width of bunches, every bunch being allowed to swing just clear of its neighbours. I can only advise "G." to place a layer of perfectly dry ashes or some other non-conducting material between the brickwork of the stove-hole and the flooring of his room, and if the flue passes through the room, to divert this if possible.

FRUIT FARMING.

4638.—No doubt fruit farming will pay if properly managed. Plant none but good sorts of every kind of fruit, and aim at having the finest fruit; think more of quality than quantity, and try and open up local trade. There is far too much of sending all fruit to Covent-garden, which has the effect of glutting the market, resulting in poor prices. But if you can convince market ealesmen that your fruit is of the best quality and honestly graded you will realise good prices even there. It is a mistake to plant many varieties of one kind of fruit; find out what sort succeeds well, and plant that in quantity. I will give you an instance of what is meant. Here, in this garden, Lord Suffield Apple does not flourish, but Lord Grosvenor does. I have but three trees of the former, but I have 500 of the latter. The same rule holds good with all kinds of fruit. If Golden Drop Gooseberry gave good results I should plant it largely in preference to others. As you have bought the land the first thing to do is to provide shelter from east and south-west winds. The former injures the blossom in the spring, and the latter knocks the fruit off in the autumn. South and northerly winds do not

Mr. Dodd's tube for Grapes.

so much matter, but if shelter can be easily provided so much the better. The most rapid-growing tree is the Black Italian Poplar. This should be planted 10 feet apart on the outer edge or boundary. A row of Austrian Pines, 8 feet apart, should be planted inside the Poplars. These are intended for the permanent shelter, the Poplars to be cut out as necessity requires. For the present allow the hedges to grow high; they may be useful for shelter. If you cannot obtain any reliable information as to what sorts of any kind of fruit succeeds in the neighbourhood, you will have to test that yourself. I should plant about 3 acres at first, commencing with the Grass-land, if this is the more sheltered. I should either farm the arable land or plant it with vegetable crops. Nothing is more profitable than early Cabbage, Runner Beans, Lettuce, and Beet. I should plant a few PLUM-TREES to test the varieties and manner of growth, but should not do this extensively. Standard Damsons would, however, be safe. These would succeed in the most exposed part, and would provide some shelter for other fruits. It is difficult indeed giving advice about numbers of any particular variety, but I will give a list of varieties that are likely to succeed in such a soil as that named, leaving the quantity of each to the owner to determine. I would strongly urge that the best trees are the cheapest in the end. Do not be led away with so-called cheap bargains. Go to a well-established firm of nurserymen and pay a fair price. Trees from two to four years old are the most suitable; these should be purchased for £10 per 100—bush Apple-trees for instance. Standard Apple-trees should be planted 30 feet apart, with a bush tree in between and complete row of bushes between the standards at 15 feet apart, all ways

One or two rows of Gooseberry-trees and Currants can be accommodated between the Apple-trees. If one row of these small fruits were planted there would be space enough left for a couple of rows of Daffodils between the fruit-trees. This intermediate crop pays well, the flowers sell readily, and the bulbs of many sorts are not expensive. The turf should be turned over, allowing it to rot, taking none away. The soil should be moved 18 inches deep where the Apple, Pear, or Plum-trees are planted if it is at all stiff or retentive of moisture. If there is any suspicion of the land being wet during the winter, plant the trees on mounds raised 6 inches above the natural level of the ground. In any case do not plant them below the surface on newly-dug soil. Add but a very small quantity of manure to the soil at planting-time, but manure the surface of all newly-planted trees with half-rotted stable-manure for at least 18 inches from the stem; 1 foot will be ample for bush fruits. Choose a dry day for planting, when the soil will intermingle freely with the roots. Prune the latter carefully if there are any damaged to induce them to make fibrous roots, which are to be preferred to fibreless ones. Do not in any case bring the soil up from the bottom to the top, but keep that which is on the surface in exactly the same position. All

STANDARD trees ought to be securely staked the same day that they are planted to prevent the roots being loosened by the tree swaying about. In conclusion, I will give a short list of varieties of each kind, which can safely be planted for trial. Although I have replied at some length to this query it embraces so much of importance that now much is left unsaid. Further details could, however, with the permission of the Editor, be given upon any point not quite clear. Apples (desert): Red Astrachan, Mr. Gladstone, *Devonshire Quarrenden, Lady Sudeley, Benoni, *Worcester Pearmain, Nanny, King of the Pippins, *Blenheim Orange, *Cox's Orange Pippin, and Cookle Pippin. Kitchen sorts: Lord Grosvenor, Lord Suffield, Duchess of Oldenburgh, Warner's King, *Mohlville, Stirling Castle, Frogmore Prolific, Golden Spice, *New Hawthornden, Golden Noble, Bismarck, Mero de Ménage, *Wellington, Lane's Prince Albert, *Newington Wonder, *Brentley's Seedling, and *Alfriston. Those with an asterisk attached are best for standards. Pears may succeed in the loamy soil. I should plant a few bushes on trial of the following kinds: Williams' Bon Chrétien, Benrô d'Amenlis, Louise Bonne of Jersey, Marie Louise, Pitmanston Duchess, Doyenné du Comice, Duchesse d'Angoulême, and Ne Plus Meuris. Plums as bushes: Orleans, Victoria, Belle de Louvain, Pond's Seedling, Prince of Wales, and Rivere' Monarch. Damsons: Earleigh and Prune are the best kinds. Carter's Prolific and Superlative are the best Raspberries. Lee's Prolific is difficult to beat as a Black Currant. Whinham's Industry, Golden Drop, Keepeake, Faithful, and Crown Bob are good Gooseberries. In all cases I have placed the varieties in their order of ripening. S. P.

4603.—Early Vines.—From the query it is difficult to know what are termed early Vines. If

Thomby mode of fixing the bottles.

those that ripen their fruit in July are called early, the month of November will be soon enough to prune. If the fruit was ready to cut in May, about the middle of October will be soon enough. Very often such plasters as clay, sulphur, and I lime are mixed together for painting the rods with, but these ingredients are entirely unnecessary, and, indeed, quite useless for the purpose they are intended for—destruction of insect pests. The best way to cleanse Vine-rods is by

thoroughly scrubbing them with a narrow hard brush, using water heated to 100 degs., dissolving in it some soft-soap. If the work is well done, working the brush around the spurs carefully, there should not be many insects left alive. A second washing should settle the stragglers. If there is any suspicion of the presence of mildew or red-spider upon the foliage or wood during the past season, the rods might be painted over with sulphur made into the consistency of paint with advantage, as sulphur is by far the best remedy for mildew and spider also.—S. P.

APRICOTS.

WITH regard to the richness and lusciousness of well-ripened Apricots there can be no two opinions. They may not be so generally popular as Peaches, especially if the latter are grown under glass, but there are plenty of good judges who prefer Apricots to any other kind of fruit that may be placed before them. Why, then, are they not more grown by amateurs and cottagers? That Apricots will not succeed on all soils and in all climates must be conceded, but very few can say for certain that they will fail in their particular locality, unless they have made an intelligent attempt to grow them. The best advice that can be given to amateurs is to ascertain what has been done by professional gardeners in their respective neighbourhoods. It is somewhat difficult to decide exactly what soil best suits Apricots, but with me they do remarkably well in a medium loam, too much clay or too little of it in the soil apparently being fatal to longevity. The worst failures that have come under my notice have been in the Weald of Kent and Sussex, on the heavy clays of Essex and Middlesex, the chalky soil of Wilt, and the hot gravels that crop up in various districts. On the other hand, in many parts of Derbyshire, Leicestershire, Oxfordshire, Worcestershire, Shropshire, Gloucestershire, Somerset, Dorset, Devon, and Cornwall, Apricots thrive admirably, being quite as easily grown as Plums. Of the eastern counties generally I have had no experience, and should be glad to hear whether or not Apricots could be successfully cultivated in any of them. Not a little depends in all cases upon the choice of site. The trees must have the benefit of wall or fence shelter, and neither low nor cool walls or fences answer well. The aspect ought to be nearly or quite south, all the sunshine possibly being needed by the trees, or otherwise the wood fails to ripen properly, light crops being one of the sure consequences of this. In some of the midland counties mentioned cottagers grow Apricots on the sunny gable-ends of their houses, and occasionally they are to be seen on the fronts, the spaces between the windows being occupied by the trees. So well do the trees succeed in these positions, a free extension of growth evidently suiting Apricots well, that not a few of the owners frequently sell enough fruit to nearly or quite pay the rent. Instead, therefore, of so many houses, stables, and other sunny walls and fences being either devoted to Plums, or worse still, not utilised at all, why not try what can be done with the choicer Apricots? A sunny site is indispensable, and next in importance comes the necessity for a well-prepared root-run. Few amateurs probably will err in giving the trees a too rich compost, though many professional gardeners have done so, the consequence being a rank, unfruitful growth. More probably the mistake will be made in not treating them with sufficient liberality. Too much moisture, especially in the autumn, is injurious, but planting in raised borders is a simple way out of this difficulty. Quite fresh turfy loam is all that need be given the trees at the outset, and this not being forthcoming, substitute the best ordinary garden soil procurable, that of a moderately strong character best suiting Apricots. Open holes for each tree not less than 4 feet square, and to a depth of about 18 inches, with intervals of 12 feet between. Remove all soil that is but little better than clay, and also any excess of gravel or stones there may be. Return the top soil into the bottom of the hole, working a little fresh soil into this, and make it somewhat firm. Then add sufficient fresh loamy soil to raise the back 12 inches above the ordinary level with a slight slope to the front, this being all the preparation needed, though if the soil be

poor a liberal addition of half-inch bones and some burnt garden rubbish will act most beneficially. As far as size of fruit and quality are concerned, Moorpark is much the best of all Apricots, but, unfortunately, it is also the most fickle, the trees being liable to gum badly, the limbs dying off wholesale. Hemskirk produces large fruit very freely, also possessing a good constitution, and if only one tree is planted let it be of that variety. Royal has been known to succeed where other varieties have failed, and both that and Shipley's are well worth a trial. A fairly good dwarf fan-shaped tree can be bought for 3s. 6d., and a fine specimen for 5s., the quickest return being had by planting one of the latter. If economy be the order of the day, then order maidens, these being usually sold at 1s. 6d. or thereabouts. Prior to planting cut away all bruised ends of roots, and cleanly cut across the broken ends in order to facilitate healing. Avoid deep planting. The collar of the tree ought to be nearly or quite exposed and the roots evenly distributed throughout the soil, the reckless plan of setting a tree in a hole and shovelling the soil on to the roots so as to mat them together being most reprehensible. It pays well to surround the roots with a little fresh light compost, some of the residue of a garden fire or another being particularly congenial to them. If the soil is at all wet, avoid trampling on it, and in any case give newly-planted trees a mulching of straw litter in order to exclude severe frosts.

PRUNING the trees is not so much of a mystery as many appear to imagine. All the same it is a very important detail, and I will do my best to describe it sufficiently. A good trained tree would be furnished with from eight to twelve branches, all of much the same size, and whether there be few or many, it is advisable to lay them all in to their length (though not till the ground has settled somewhat), and exactly as previously trained. Cutting back the branches rather hard is a loss of time, the trees very probably being two or three seasons before they again attain their original size. Even lightly shortening the branches is a mistake, though, if the points are green, that portion should be cut off. Laid in to their full length, either lateral growth or fruiting spurs will develop at every joint, but those pruned are liable to break near the ends, the lower parts being quite naked. During the summer all lateral growths other than one or two on each branch (these being required for furnishing blank wall space as the trees extend) should be shortened back to a length of about 4 inches, and further reduced to a length of 1 inch at the winter pruning. No fruit ought to be expected or allowed to form during the summer following upon planting, but if all goes on well a few may be had in the following year. Maidens or trees that have made one unpruned shoot must not be allowed to remain intact, but should unhesitatingly be cut back to within 4 inches of the point of union of the graft or scion with the stock. From the resulting shoots select four of the best placed, and carefully train these in an oblique direction and well clear of each other. Next winter these branches ought to be shortened to about one-half of their length, and each giving two well-placed shoots, the foundation of a good tree is laid, no more shortening back being needed. Let the tree extend freely, laying in fresh branches according as there is good space for them, and they will soon become very profitable.

Apricots succeed in greenhouses better than most gardeners, amateurs or otherwise, are aware. In very many cases where glazed structures are erected against walls of dwelling-houses or high back walls of any kind, the latter might well be utilised for the culture of Apricots and other hardy fruit. Standard-trained trees can be bought, these being the best to plant where there are front or back benches or stages in the way. Prepare the borders, plant, prune, and train exactly as advised in the case of open-air trees, and they are almost certain to do well. They must, however, be kept well supplied with water at the roots, and not be forced, ordinary greenhouse treatment best meeting the case.

H.

4640.—Grape-vine in a greenhouse. The number of bunches is too many for a vine but five years old; half that number

well coloured would have been more creditable. A Vine of this age, and carrying such a heavy crop, could not be expected to colour the berries. There are several causes to be advanced for the cracking of the berries, although Black Hamburgh does not crack its berries, as a rule; in fact, it is exceptionally free from this evil. If the skin of the berries is covered, or partly covered, with rust-looking matter, this would cause them to crack; the skin is injured and cannot expand. Rust is caused generally by inattention to ventilation early in the morning. The vinery is kept closed until the sun induces the temperature to rise inside the house so much that the condensed moisture falls upon the surface of the berries, and if air is admitted to the house by opening wide the ventilators at one time instead of gradually, the temperature suddenly falls, causing a chill to the berries. Mildew may have caused the berries to crack; where this fungus fastens itself to the berries the skin tissues are injured so much that the berries crack instead of swell regularly. Do not syringe the Vines at all after the bunches are in bloom; water lodging on the berries with the sun shining powerfully on them also may have caused the cracking of the berries. The rods are about the right distance from the glass. The Grapes will colour in the same house with plants if the Vines are healthy and not cropped too heavily. Air should be admitted in small quantities early in the morning, increasing the supply with a rising temperature.—S. P.

4492.—Clover-seed and Strawberry-berries.—I never heard of such a thing, and should certainly not advise you to do so as you suggest. The Clover would over-run the entire bed, smothering the Strawberry plants and exhausting the soil.—B. C. R.

4651.—Fruit in a cellar.—Fruit of any kind, especially Apples, does not keep well this season, so much Fungus appears to be present among the fruit. A small speck in the skin quickly develops into a decayed place rendering the fruit quite useless. The abnormally dry summer experienced, which robbed the tree of their necessary root-support, is no doubt the cause of early decomposition. A cellar is, as a rule, a good place to keep fruit in, provided it can be ventilated freely for a time until the sweetening of the fruit ceases, when little air will be required. I lay mine in heaps on straw. Turn them carefully over after they have been there three weeks to remove any affected fruits which contaminate those near them.—S. P.

A cellar is not a bad place for keeping fruit if it is well ventilated, cool, fairly dry, and the temperature even. Possibly your fruit has rotted through careless gathering. The fruit-room is often blamed when the gathering is at fault, or the fruit is not used in its proper season. The great thing is in keeping fruit to maintain a cool, even temperature, and lay the fruit out in single layers, not heaping them up as is too often the case. When this is done a bad fruit will promote decay in the whole heap and create much mischief. Look over the stores at frequent intervals to pick out those that show signs of decay, and which may be used at once.—C. T.

A dry cellar is an excellent place for late Peas and Apples, if free from woodlice and mice. It should be mentioned that the early autumn Peas do not keep long under any circumstances.—E. H.

4667.—Fruit-trees round a large tennis-lawn.—Espalier-trained Apples and Peas would be the most suitable kind of trees for the purpose. Not less than 15 feet should be allowed between each. There is nothing as serviceable or so good for training the trees to as a wire-trail 5 feet high, made with No. 3 wire, strained tightly to stout iron posts let into the ground at each corner with substantial feet and flat iron standards, 15 feet apart, to support the wire between. The wires ought to be 10 inches apart, or according to the distance the side branches are apart. Horizontal-trained trees are preferred for espaliers. Early in November is a good time to plant; the soil should be trenched 2 feet deep, keeping the surface soil on the top. Plant the trees so that their roots are within 3 inches of the surface, choosing a dry day for the purpose, so that the soil will readily mix with roots. Any bruised or broken roots should be carefully pruned to a sound part, indoling them to make fibrous roots from the same place. If a spadeful or two of road-grit, decayed leaves or vegetable refuse, which is added a small quantity of wood-ashes, can be used for covering the roots,

as much the better. I prefer this to adding manure to the soil; except in cases of extreme poverty I do not advocate the employment of manure; at planting-time it is too apt to induce growth that is too rampant to become matured thoroughly, and this is one of the most important points to study in fruit culture. A mulching of half-decayed stable-manure, laid on 3 inches thick, will preserve the roots from frost during the winter as well as prevent the evaporation of moisture from the soil during the summer following if hot and dry. The following is a good selection of sorts classified in their order of ripening: Apples (dessert): Irish Peach, Lady Sudeley, Devonshire Quarrenden, Worcester Pearmain, King of Pippin, Cox's Orange Pippin, and Starmer Pippin. Kitchen varieties: Lord Grosvenor, Keswick Codlin, Echinville, Duchess of Oldenburgh, Warner's King, Mère de Ménage, New Hawthornden, Lane's Prince Albert, Newton Wonder, and Alfriston. Pears: Jargonelle, Williams' Bon Chrétien, Marie Louise, Pitmaston Duchess, Bourré Dieul, Winter Nellis, Duchesse d'Angoulême, Doyenné du Comice, and Josephine de Malines, with Cotillac for stewing.—S. P.

CHRYSANTHEMUMS.

SEASONABLE NOTES.

THE cultivator must now be nightly on the look-out for enemies in the shape of earwigs, cockroaches, caterpillars, slugs, and woodlice. This may seem a long list to have to contend with, but each is in its case. Directly the blooms begin to expand, one or other of these pests take a fancy to the tender morsel of petals. Earwigs are the greatest pest. It is surprising what amount of depredation is caused on one bloom during a single night by earwigs. Trap them by placing Broad Bean stalks 1 foot long amongst the leaves of the Chrysanthemums, examining them every morning. By this means many may be destroyed; but the best way to catch them is by going round after dark each night quietly with a light when they are busy feeding on the petals. They must be caught quickly. Nothing is better for the purpose than a pair of tweezers. The least shake of the plant and they secrete themselves among the petals and are not at all easy to discover again. Woodlice in some places are troublesome, as they eat the florets from the under-side of the flower. The damage is not always seen until the flowers are spoilt. When the plants are in vineries this pest is the most numerous; the mulchings of manure used therein for the vines is just the place for them to harbour, as it is generally dug on the surface in some parts of the house during the winter. Hand-picking from the flowers is the only remedy, and where they are numerous this must be incessantly carried out. Slugs disfigure the flowers by crawling over them, and in some cases they eat them. Where any trace is seen of them, either on the flowers or leaves, or even on the pots during the day-time, they are almost sure to revisit that particular spot the next night. In this manner they can be caught after dark. Some bran laid on the top of the pot will not act as a bait for them. Cockroaches where numerous are sure to find out the blooms, which are soon spoilt when three or four commence to eat them. They are rather difficult to catch when feeding, as the moment the light is turned on them off they go. When the plants are so situated that they are standing thinly about, a gentle shake dislodges them when they can be killed on the floor. Cockroaches are most troublesome to plants that are placed in heat to push them along—for instance, the members of the Princess Teck family often require hastening to have them in bloom at the same time, these varieties requiring to be grown from late buds necessitate their being generally later than many others. All of this type bear forcing in the plant stove remarkably well, and it is while they are in such structures that the cockroaches are the most troublesome. Green caterpillars are sometimes a source of annoyance; except by chance in moving a plant, the night is the only time to discover their whereabouts. It will be seen that the grower of Chrysanthemums for exhibition has many enemies to contend with, all of which must be subdued if perfect blooms are expected.

4600.—Losing foliage of Chrysanthemums.—It is common for this variety to lose its foliage this year, especially on plants that are cultivated for the production of large exhibition blooms. This I attribute entirely to the season. The abnormally hot and dry weather is, no doubt, the cause. The former rendered the roots too hot in the pots, and the latter prohibited atmospheric moisture too much. I do not think that the blooms of this variety generally will be up to the mark either; the loss of foliage so early caused a shock which must tell upon the quality of the blooms later on. This, coupled with the fact that the crown, or second bud, formed too early to warrant cultivators to "take" it with any degree of certainty, the consequence is that in most cases the third bud has been depended upon; these give smaller blooms.—E. M.

— You are probably growing your plants in pots of too small a size. Avalanche is a strong grower, and requires plenty of pot-room. The pots should not be less than 9 inches in diameter; 10 inches will be better.—E. H.

RULES FOR CORRESPONDENTS.

Questions.—Queries and answers are inserted in *GARDENING ILLUSTRATED* free of charge if correspondents follow the rules here laid down for their guidance. All communications for insertion should be clearly and concisely written on one side of the paper only, and addressed to the Editor of *GARDENING ILLUSTRATED*, 57 Southampton-street, Covent-garden, London. Letters on business should be sent to the Publisher. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Unanswered queries should be repeated. Correspondents should bear in mind that, as *GARDENING ILLUSTRATED* is sent to press some time in advance of date, they cannot always be replied to in the issue immediately following the receipt of their communication.

Answers (which, with the exception of such as cannot well be classified, will be found in their different departments) should always bear the number and title placed against the query replied to, and our readers will greatly oblige us by advising, as far as their knowledge and observations permit, the correspondents who seek assistance. Concise, plain, and concise answers to queries should be given, and those who reply would do well to mention the localities in which their experience is gained. Correspondents who refer to articles inserted in *GARDENING ILLUSTRATED* should mention the number in which they appeared.

4495.—Grafting.—Which is the best time and method to graft Apple and Pear-trees?—B. J. F.

4600.—Cider press.—Will anyone kindly tell me where I can get a good portable cider press suitable for a small orchard?—H.

4607.—Plants for a cold greenhouse.—What plants besides bulbs can I grow in a cold greenhouse without any heat or warmth?—Youko, Kent.

4608.—Cherry-trees dropping flowers.—Will someone kindly inform me how to prevent Cherry-trees from dropping all their blossoms?—B. J. F.

4609.—Rose cuttings.—I am having a long trench dug deep for bush roses. Will someone please to give me the names of twelve best Tees and twelve best Parquetals?—A. Nooks, Surrey.

4700.—Aranaria (Monkey Puzzle).—Will someone be good enough to tell me how to treat this tree? The branches four or five up are almost dead. Is it fresh soil that is required?—Stocks.

4701.—Hardy Asclepi.—Would any of your readers inform me if hardy Asclepi will stand out-of-doors, or will be any better for pruning? I should like to keep mine rather small if it did not injure them.—A. A.

4702.—Insect on Vines.—I noticed in my vineyard that there are a great many white woolly spots in the crevices along the canes. Will any person kindly say if this is an insect, and if so, how to banish it?—Novica.

4703.—Enlarging a garden.—I am about making my garden larger by a siding extra ground, which wants green stuff dug in. Please let me know what seeds I am to sow for plants to dig in, and how late in the year I can do so?—Youko, Kent.

4704.—Roses for show.—I intend growing some Hybrid Perpetuals for competition at our local show. Will someone kindly favour me with the names of a dozen or so that would be most suitable for that purpose? Also, which would be preferable, bushes or standards?—Hvrasin.

4705.—Pear-tree with cracked fruit.—I have a Pear-tree which has produced a large crop of fruit of a very delicious flavour, but they were all more or less cracked, and also the bark at the trunk of the tree. Will anyone give me a means to prevent the cracking?—B. J. F.

4706.—"Geraniums" in winter.—I should be glad to know how I could keep my "Geraniums" through the winter. I have only a small garden (several dozen "Geraniums" in 16) on greenhouse or frame of any kind to place them in, and desire information as to when and how to pot them and preserve them if possible.—F. F., Richmond.

4707.—Campanulas in pots.—I would be much obliged to any person that would give me a few hints on the proper treatment of Campanulas? I have *C. fragilis* and *C. garganica* growing in pots in a cold frame, struck from cuttings in spring, and they do not seem to be doing well. They never flowered this year. Is there any hope for keeping them through the winter in the frame, or are they quite hardy? If so, will they do better in running or sanded?—Novica.

4708.—Plants for a rockery.—Would someone kindly tell me of some plants that would grow well on a rockery covered by large trees, mostly Birch and Horse-chestnut? The soil is loamy; but that could be removed if necessary, so I have done this for the Ferns. I have tried ordinary rock creepers, but the drip from the trees kills them in the winter.—A. H.

4709.—Gathering Mushrooms.—Will someone kindly say how natural Mushrooms should be gathered? Should the heads be cut off and the stalks left in the ground? This is the usual way, but it is said that the stalk, if left in the ground as it decays, destroys the adjacent spores. Which is right? Again it is said—Do not gather your Mushrooms too closely, but always leave some. If you gather all you can you will have no crop next year. Is there anything in this?—G. H. T.

4710.—Climbing Roses.—I have two Roses, apparently climbers from the long, thin shoots they are sending. They flowered white, with four or five buds in a cluster, very small and semi-double. How should I treat them to improve size of flowers and habit? They face east and are in a narrow corner. Have I in part stems of four Rose-plants, vigorous growers. One last year I cut down to the ground; another I layered all round; the others I left alone, and they have sent shoots yards long up the wall and all over the place, but not a flower has ever appeared. Faces south, in shelter; end of shoots always covered with green-fly. What can I do with such rubbish? Enclosure C, vigorous dwarf, out a flower. What is it? Have used peat-iber from stable, but kept long, and house slops.—Old Sailor.

4711.—Various Roses.—I, I have thirty or forty Rose-trees, planted two years ago, various sorts, growing vigorously, but flowering very little. Will they be planted too deep, as I put them in myself, and from what I have heard and read from your paper I have been uneasy all summer about this? Would it do to replant near the surface this winter? Would it be advisable to cut up a bushy plant with branching root, and stems growing direct from root? Several that I planted had very large roots compared to the pencil thickness of the stems. They have never flowered (smooth stem). As I expect you to say "cut them out," would they do to bud or graft? 2. Recommend me a few Roses that would bloom well in the hands of an amateur—not-and-come-again sorts, climbers or dwarfs, white or black, but Roses.—Old Sailor.

To the following queries brief editorial replies are given; but readers are invited to give further answers should they be able to offer additional advice on the various subjects.

4712.—Mushrooms (A. E. P.).—These are not the true Mushroom *Agaricus campestris*, but the clove ally, *A. avasella* (the Horse Mushroom). It is excellent, and very good both for frying and ketchup making. Examples from under trees are sometimes a little indigestible.—W. G. S.

4713.—*Odontoglossum crispum* (R. C. F.).—This flower is not the true species—you may tell it by the lip being long and narrow; but it is one of the natural hybrids of which we have had so many crop out from amongst the imported crispums without being entombed! I should like it. It is a very pretty variety, and well deserves attention. You may call it what you please.—M. B.

4714.—New Zealand Flax (*Antipodes*).—You should take the plant or plants up from the open border and pot them. I have seen fine specimens stand out-of-doors in Ireland unharmed, but I do not think they would do so in the county of Hertfordshire. It makes a splendid plant for the decoration of a cold-house in winter as it requires but slight shelter to protect it from the wintry weather.—J. J.

4715.—*Maxillaria venusta* (J. Bishop).—This is undoubtedly the name of the flowers you send; but I think it is rather casual time to see it in bloom. It should be kept in the cool-house with the *Odontoglossum grandiflorum* is similar, and about the same colour, but the flowers stand up erect, which the blooms of the kind you send do not, therefore *M. grandiflora* is, I think, the most desirable kind.—M. B.

4716.—Treatment of *Dendrobium* (*James Trevelick*).—Yes; all plants such as *D. Wardianum* and *Peirardii* and the like should be kept in a cool-house at present. They may be hung up in the sunshine near in the roof glass, water being entirely withheld. *D. crassinode* and other earlier bloomers will require to be removed into more warmth somewhat before *Wardianum* and some others, of which you will see some remarks at a future time.—M. B.

4717.—*Odontoglossum grande* (G. B.).—I am thankful to my friend for sending me a flower of the species and glad to find he has done so well by following my instructions. I have given him the name required, and say the flower sent represents a very good variety of the plant. I have had specimens with some twenty and thirty flowers all open at one time, which is a sight worth seeing, and my employer years ago called them "Tiger-flowers."—M. B.

4718.—*Zygopetalum Gauthieri*.—*James Brown* sends this for a name, which I here give. It is a fine form of the species known by the name of *Z. maxillare*, which produces a rich violet-blue lip, a colour which is rare in hybrids, and is always highly prized. It grows on the living stems of Tree-Ferns, and, as these are warm-house species, it is best to grow them upon one which will thrive and give shade to this plant and to various others which stand in the vicinity.—M. B.

4719.—The coming winter.—*Thos. Carson* writes me a long letter asking my opinion respecting the winter that is coming; but I do not aspire to the gift of prophecy, and so cannot answer your questions. The fact of the weather being so abnormal would rather upset the nerves of anyone, so I attribute the fears and predictions of "T. C." to this cause. I advise you to have everything set in order and in readiness for the severe weather you anticipate, and all will be well; but do not repeat the letters for a "prophet has no honour in his own country."

4720.—**Cost of an Orchid collection (M. M.).**—This is a very difficult question to answer in a definite form as so much depends upon what one calls a collection. Some would say a dozen kinds was a good collection, whilst others would require hundreds of species to form a collection; but if "M. M." would take, say, a £5 or a £10 note to some nurseryman known to have a large quantity of Orchids, say he was a beginner in Orchid growing, he would be treated well, and he should advise him of the heat he has at command so that he could better fit him with those which would suit him.—M. B.

4721.—**Dendrobium nobile (No Name).**—If the plant has done growing the plant should be kept cool and tolerably dry; but if the growth is not yet made up it should be placed in the warmth until it has, when it should be placed in the cool and kept tolerably dry; but as this species does not flower upon the wood it has just made, but upon that of the previous year, it must not be kept so dry as to cause the growths to shrivel from some cause, either accidental or from some mismanagement. They do sometimes produce their flowers upon the stems of the current year's growth, with their leaves upon them.—M. B.

4722.—**Oncidium Crosses.**—James Charlton sends a flower of this plant for a name, saying it was brought with some others from Jamaica by a friend of his, which might be true; but yet it may not be a native of that island, and this would not be the first time that an Orchid was found in that island that was an introduced species. I do not know if anyone has divulged the spot whence this plant comes, but it is usually considered to be a native of the Organ Mountains, near to Rio Janeiro. It is rare in collections. The flower is of a beautiful bright golden-yellow, having a dark blackish-purple band round the crest of the lip. It should be grown on a block of wood or in a very small earthenware hanging-pan; it requires the heat of the Cattle-house.—M. B.

NAMES OF PLANTS AND FRUITS.

* Any communications respecting plants or fruits sent to me should always accompany the parcel, which should be addressed to the Editor of GARDENING ILLUSTRATED, 37, Southampton-street, Strand, London, W.C.

Names of plants.—Down East.—1, *Cyrtolium Fortunei*; 2, *Adiantum Ghiesbreghtii*; 3, *Adiantum concinnum*; 4, *Aspidium tuberosum*.—G. B.—1, *Chontolossium grande*.—James Brown.—*Zygopetalum Gaultieri*.—A. Scott, Northumberland.—1, *Pteris arvensis*; 2, *Asplenium fimbriaefolium*; 3, *Cyperus alternifolius*; 4, *Pteris serrulata*; 5, *Phlebodium aureum*; 6, *Polyadichum Woolastonii*; 7, *Adiantum cuneatum*; 8, *Anthericum variegatum*; 9, *Anemula*; send when fertile; 10, *Cissampelos*; send fertile specimen.—H. Breckerton.—1, *Nephrrolepis pedunculata*; 2, *Asplenium elatum*; 3, *Pteris escharella*; 4, *Myriophyllum verticillatum*; 5, *Phacopleris hastifolia*; 6, *Gomopteris latragona*.—Rogers.—1, *Lycopodium obtusatum*; 2, *L. alpinum*; 3, *Athyrium Filix-femina*, broad-placed variety; 4, *Aspidium foetidanum*.

BEEES.

SEASONABLE NOTES.

IN the successful wintering of Bees much depends upon stocks being strong in numbers, and heavy in stores. Stocks that are not strong should now be joined two or three together. Bar-frame hives can be strengthened by introducing combs of brood from very strong stocks, or two colonies can be united by placing the combs of one hive with the adhering Bees in the midst of the colony it is wished to join them to. Stimulative feeding may now be carried on in order to induce the queen to continue laying, and thus ensure a number of young Bees for wintering. Feeding should be discontinued before the end of October. The syrup used for stimulative feeding should consist of sugar and water, the proportions being 7 pints of water to 10 lb. of sugar; that for feeding up for winter, 5 pints of water to 10 lb. of sugar, boiled for a few minutes, with the addition of an ounce of vinegar and half an ounce of salt.

UNITING STOCKS IN STRAW SKEPS.—Bees know each other by scent; if, therefore, all that are to be united be first sprinkled with minted syrup, it prevents them discovering which are strangers, and so no fighting takes place. In uniting, we therefore smoke and turn up the skep containing the Bees that have been driven, and sprinkle them with thin syrup scented with peppermint, then smoke the stock to which they are to be united, and sprinkle these Bees also with scented syrup, propping up the edge of the hive with a wedge or stone, then with a sharp and sudden movement throw the driven Bees against its entrance, first spreading a newspaper or cloth in front to receive them, they will run into the skep and become peacefully united, or the driven Bees may be shaken upon the combs of the stock hive, the latter, of course, having been first inverted, and then replaced upon its stand, propped up a little to prevent the crushing of the Bees that are on its edges. The queen, if possible, should be removed from the driven lot. The two hives, that are to be united should be previously brought gradually

together, about 3 feet per day. If a hive be moved a greater distance than 3 feet daily, many Bees will be unable to find their home on their return from the fields and the loss of Bee life will be great.

DRIVING CONDEMNED BEES.—Driving stocks of Bees to save them from the old-fashioned and cruel "brimstone pit performance" mostly practised by cottagers, is much to be commended. The skep to be operated upon should first have a little smoke blown into the entrance; this will alarm the Bees and cause them to fill themselves with honey from the unsealed cells. In this gorged condition they become quiet and easy to manipulate. The skep may then with safety be inverted and placed in a pan or pail to steady it; a flat-topped skep can of course be placed on a flat surface. Then an empty skep is placed upon the stock skep, bringing the edges together at the point toward which the combs run, and an iron skewer pushed through the run of the empty skep into the one below, forming a kind of hinge, and a strip of wood with nails in the ends, or "driving-iron," if used, are fixed on either side to keep the empty skep up like an open lid. The sides of the stock hive are then rapped upon with the open hands all round with sufficient force to jar the combs without displacing them. A loud buzzing is soon heard, and the Bees are seen rushing up into the upper story. If a sharp look out be kept, the queen can be secured while going up in the crowd. The skep of honey is thus secured with little or no loss of Bee life. The Bees can then be united to other stocks, which will greatly strengthen them for the winter.

PREPARING HIVES FOR WINTERING.—Abundance of sealed stores, a prolific queen, a large number of young Bees, and sufficient ventilation in the hive without draught are the main points to be observed in preparing stocks for winter. Coverings for frames may consist of two or three thicknesses of sacking, upon which may be placed a piece of thick carpet or felt. Where enamel cloths have been used over the tops of frames they should now be removed, and the propolis scraped from the top bars before placing on the winter coverings. A bottomless box, the size of the top of the hive, 4 inches deep, having a piece of calico tacked on to the bottom, and filled with cork-dust or chaff, makes a good winter cover in place of quilts. Double walled hives may have the spaces filled with cork-dust to assist in keeping an even temperature within the hive, and to prevent the escape of heat. A strong stock should be wintered in eight or ten frames of comb, two-thirds of which should contain sealed food. Combs of pollen weigh almost as much as those filled with honey, and as pollen is much more abundantly stored in some hives than in others, the weight of a hive is not a safe criterion. The quantity of honey sufficient for wintering upon can only be decided by inspection. It is not wise to leave any hive for the winter with less than 20 pounds of stores.

THE "FLOWER GARDEN" AT KEW.

I HOPE the improvements so manifest as regards hardy flowers in many parts of the pleasure grounds at Kew will not stop at the flower garden in front of the Palm-house. Two large beds of common Beetroot form the central feature of this, and masses of flowerless Pelargoniums and dots and stripes of red and blue are not worthy a place as a flower garden in the Royal Gardens at Kew. If the idea existed that a garden in such a position cannot be made beautiful through the aid of nobler types of vegetation, it is quite erroneous. That is a position above all others in which beautiful things, gracefully grouped and well grown, would tell best. The scarlet Pelargonium in the dry soil of Kew is as well worthy of a place as any other flower, but it is only one of the many beautiful things that should find a summer home there. Some of the prettiest beds of half-hardy flowers as in the parks might well find a place here, and are far before the Beetroot, &c., of the present year. In such a flower garden it would be well to see the best of the half-hardy flowers also. Moreover, where the collection is so rich in sub-tropical and other half-hardy Palms, Oranges, Oleanders, Datura, and many beautiful plants which enjoy, and are all the better for, a sojourn in the open air during the summer, it would be well to make artistic use of them, and put them in groups not only in the flower garden, but also in the unused parts of that waste of gravel around the Palm-house. So, too, that piece of water between the museum and the Palm-house should be a garden of handsome water flowers which no Victoria regia house in the world would equal in beauty. Not only Water Lilies and beautiful water flowers of the northern world have we to enrich such water now, but, owing to our friend M. Latour-Marliac, we have a noble series of hardy hybrids, groups of which in such a position would give delightful pictures. The nucleus water-fowl should be taken somewhere else—to the Zoo, perhaps. The banks of this water should be planted with the many fine plants, such as *Spiraea venosa*, which delight in the waterside, flower at the same time as the Water Lilies, and would form with them a garden worth seeing. The flowering herbaceous plants for the waterside are numerous and handsome, and, seen in bloom at the same season as the Water Lilies, give offsets which few people have any idea that gardens are capable of. Then, alter the Iris and Globe flowers and other handsome flowers of the waterside, there are many plants with fine habit, as the Gunners, great Reeds, some hardy and free Bamboos, Royal Ferns, great Water Dock and Bulrushes, and the more graceful and smaller Reeds, Arrowheads and Reed Mace. I not only wish these things for themselves, but for the good it would do in the minds of the many people who see Kew. Unhappily, the idea that a flower garden can only be formed of a few things in a stiff way is still very common even in the "fine places" in the home counties, and a real flower garden at Kew would do much to

dispel it. Thousands of gardens would be benefited for good if the right thing were done in the flower garden at Kew, and it is very easy to do it there. W. R.

CHRYSANTHEMUMS.

CHRYSANTHEMUMS FOR SHOW.

4619.—Below I give the names, as desired, of twenty-four varieties, all suitable for exhibition, and of fairly easy growth. It would be impossible in a short note like this to give details of culture during the whole season; all I can do is to give the salient points in the cultivation of the plants for large blooms. Stout sucker-like growths, 3 inches long, make suitable cuttings. These, taken off and inserted singly in 2½-inch pots in sandy soil any time during the month of December, will lay the foundation for future blooms. At no time during their early stages of growth should Chrysanthemums have artificial heat. The cooler the quarters the more stocky the growth, and less liable to injury from wind also. Do not top the plants at all, but allow them to grow away uninterceptedly until they make their first natural break, from which three of the best shoots are selected upon each plant, removing all other growths as fast as they appear. Eventually then each plant will carry three blooms. Shift the plants on into larger pots until those 9 inches or 10 inches in diameter are reached. A compost of three parts fibry-leaf-mould to one each of partly decayed horse-manure and leaf-mould, with sufficient sand and charcoal to keep the whole porous. Press the soil firmly into the pots to induce the plants to make stocky growth. An open position should be provided for the plants during the summer, where they would make growth that should not be troublesome to masters. Remove the plants indoors before they are caught by an early frost. A position near to the glass is best. The soil in the pots should be kept constantly moist, varying the clean water with liquid-manure every third day. Insects and mildew must not be allowed to obtain a firm footing, or the growth will be checked. Tobacco-powder dusted on the parts affected will generally destroy the former, while flowers of sulphur will destroy the germs of mildew on the leaves if it be sprinkled on the parts affected. Japanese: *Avalanche* (white), *Sunflower* (yellow), *Edwin Molyneux* (orange and gold), *Viviseid Merle* (bluish-mauve), *Col. W. B. Smith* (old-gold-yellow, suffused with terra-cotta), *Mrs. Falconer Jameson* (orange-red and gold), *W. H. Lincoln* (golden-yellow), *Beauty of Exmouth* (ivory-white), *Etoile de Lyon* (deep lilac-rose), *Mons. Bernard* (purple-violet), *William Seward* (intense velvety-crimson), *Mrs. A. Hardy* (pure-white, with bluish forets), *Incurved*: *Empress of India* (white), *Queen of England* (bluish-white), *Lord Alcester* (primrose), *Alfred Salter* (clear lilac-pink), *Hero of Stoke Newington* (rosy-pink), *Jeanne d'Arc* (bluish-white, tipped purple), *Miscellaneous*: *Haggas* (soft-white), *Princess of Wales* (pale-rose), *Violet Tomlin* (bright violet-purple), *Prince Alfred* (rose-carmine), *Mrs. Norman*

Davis (rich golden-yellow), *Mrs. S. Coleman* (bright-rose, shaded yellow in the centre).—E. M.

4608.—**Chrysanthemum from seed.**—"Intersected One" would do much better to buy a packet of seed from a reliable source than attempt to save seed himself. Specially built houses are required to save seed really well, and some art is necessary in hybridising the blooms properly to obtain the right kind of cross. Sow the seed in a box of sandy soil at the end of February in a gentle heat, covering the box with a piece of glass to arrest the evaporation of moisture from the soil. Directly the plants are large enough to handle, pot them off singly in thumbs, place them on a shelf close to the glass in a temperature of 55 degs. When the pots are full of roots shift the plants into pots 4 inches in diameter and again into others 7 inches across, using a compost of loam two parts, one of partly decayed horse-manure, with sand enough to keep the whole porous. At the second potting give the plants cooler treatment, finally placing them out-of-doors with the remainder of this family in an open, sunny position. One great aim all the way through is to induce a stocky habit of growth. When the plants make their first natural break, by the formation of a bloom-bud at the point of single stem, three additional shoots should be selected, tying them loosely to one stake in the centre, removing all other growths as fast as they are made, restricting the growth to these selected shoots. Each will bear one bloom in the centre, other beds will form at the side; but if large blooms only are desired, remove all but that in the centre. Place the plants under cover upon the appearance of frost, and give them a light position in a cool-house where they are to flower.—E. M.

4665.—**Carnation-seed.**—This has been a capital season for work of this kind, as the plants bloomed early and well, and the weather being so hot and dry the seed formed freely and, ripened in good time. I gathered my small harvest nearly a month ago; the pods have since been drying off on a sunny shelf, and the seed has just been shaken out. In a general way it is necessary to fertilize the blossoms artificially—those of the fine-named kinds at any rate—and even then if the weather is wet the seed will come to nothing. The best way to insure a crop of seed is to grow the plants in pots under glass, and then with the aid of a little heat in cold or wet weather they can scarcely fail to produce seed. The hard conical seed-pods must take on a deep yellow colour before they are fit to gather.—B. C. R.

—The best seed is not easily saved, as the fuller and better the flowers are so much the more difficult is it to find pollen to fertilise them with. Harrison Weir and Mrs. Reynolds Hole are not the most difficult to obtain seed from. The seed will always take about two months to ripen, and it is no use taking the pods off the plant before the seed is nearly ripe. If the pods are opened it will be seen that the seed has changed in colour, and become blackish even before the pod itself has changed. The seed is generally ripe when the pods become brownish at the top.—J. D. E.

GARDEN WORK.

Conservatory.

To a certain extent the house will be given up to the Chrysanthemum, as the main care will be made suitable for their wants. This means that just enough warmth will be maintained in the pipes to dissipate damp and permit of the ventilators being nearly always open, more or less. This, again, should be arranged that full air is given on fine, bright days, with perhaps just a crack left on at night. I do not think any Chrysanthemum-house should be altogether closed. The large number of plants which are now grown, and the high amount of attention has to be found, renders it obligatory upon the cultivator to stage his plants close together, and this of itself will generate damp, and if the air-giving is not well understood, not only the leaves will go off prematurely, but the flowers also. Damp is worse than frost. I think, in the arrangement of the plants in the house, the Chrysanthemums should be levied into groups by themselves, and the other plants, such as Zonal Geraniums, Tree-Carolines, Honeysuckles, Scabunums, Primulas (how very charming the Primula obconica is! What a pity it has a bad character!), Heaths, &c., should be grouped near the paths or close to the front lights. I generally, as far as possible, keep such things as Primulas, Cyclamens, Carnations, and lored bulbs back in other houses until the early autumn show of Chrysanthemums is over. The later flowers will be in less quantities, and by the end of November the Chrysanthemum frays will be over, and we shall be mad for other flowers. So far as regards flowers for cutting, the Chrysanthemum season cannot be too long, but to the conservatory one is not sorry when the glut is over and the lored flowers bring in a polish and sweeter of a different type. Whilst the big flowers are in the house everything else is dwarfed, so to speak. Groups of Mignonettes or Cyclamens are nowhere in the competition; but when the Chrysanthemums are thinned down one can better appreciate the smaller matter. The charm of the forced Primula Hyanthoides mixed with Maiden-hair Ferns, are irresistible in some quiet corner, and the old-fashioned Corollid glaucosa and its variegated variety are useful when flowers are scarce. Begonias will be best kept back in reserve till the Chrysanthemums are on the wane. Good-sized bushes of Begonia insignis are very effective at Christmas and later. I find young early-struck cuttings flower so much better than old plants, and I have specimens as required, but those of late years are a little pit, and lean the branches out a little. Tois Begonia is so good both for the conservatory and for cutting that it might be grown very largely when a bright state of things is required about Christmas and the New Year.

Stove.

This is usually the most interesting house in the garden at this season. There is generally plenty of colour in both leaf and blossom. Some of the earliest Poinsettias may be taken to the conservatory. A temperature of 60 degs. at night will be high enough to preserve the scarlet bracts for some time, and where Poliolepis are grown largely it will be with the view of utilizing the plants in the conservatory and for cutting. Cypripediums, after the flowers are out, may be taken to the conservatory or be used in the rooms. These are among the most useful plants for the small grower, so far as regards Poinsettias, are not difficult to manage, and the flowers last so long. Drodium noble and others which have been well ripened in a cooler house may now be brought back, and in the stove will soon throw out their blossoms all up the sides of the long pseudo bulbs. This is one of the Droids whom all having much demand for winter flowers should grow largely. Cologoye orlets is another Orchid which may easily be grown in a mixed collection in quantity, as they are getting cheaper, and will soon come within the reach of all. Competition among Imperials and growers will do this. The wonder is that with the immense stocks in the country, Orchids have not become cheaper than they are; but the demand for, and the high prices obtained for, choice Orchid flowers makes it profitable to grow Orchids for the flowers alone.

Unheated greenhouse.

Yucca in variety are very effective in pots. Y. aloifolia variegata is one of the best for network, and will be kept safely in a cool-house. Should the frost be severe and prolonged, draw the leaves together and wrap a piece of matting round it. Dracena Indivisa may be kept in this way if the pots are plunged or surrounded with something which will keep out frost. At the present moment the owner of the unheated conservatory is to clover; his Chrysanthemums are doing well, and he is not worried about the price of oats or coal. In all cases where the unheated house is a small one it will pay to make a cover of heavy cloth that can be drawn over the roof and tied to hooks screwed to the house. A few shillings will buy cloth enough to cover a good-sized house, and with care, using it only in frosty weather, it will last several years, and if, in addition to the cover, one likes to set up an oil-stove or lamp, the cost of the cover will pay for itself. This matter of covering on cold nights is worth consideration even by those who have a hot-water boiler and pipes.

Ferns under Glass.

Ferns can never be allowed to get dust-dry without suffering injury. It is perfectly true that this season Maidenhair and other Ferns which have lost form and colour are to a certain extent dried off and then set down, and for the time being it does no harm; but I should not recommend a regular practice to be made of this drying off of evergreen plants. The temperatures for stove or tropical Ferns will now be about 60 degs. at night; 45 degs. to 50 degs. day for the greenhouse species. Ferns are not so difficult to grow in a Fernery as where the atmospheric conditions are right, seedling Ferns spring up all over the place. I have one house of considerable size now filled chiefly with Ferns, and all along under the stage seedling Ferns are springing up in great numbers. No care at all has been taken with them, although I know, of course, that seedling Ferns would grow there in large numbers.

* In cold or northern climates the operations referred to under "Garden Work" may be done from ten days to a fortnight later than is here indicated with equally good results.

Strawberry Plants for Forcing.

These should now be plunged in ashes or some equivalent. Plunge up to the top of the rim and press the frost over the pots. This, if about possible, be covered with a lot of light to throw off heavy rains; this will do even better than being placed in frames. Strawberries are hardy enough if the roots are protected.

Window Gardening.

Recently potted up stuff must be kept on the side of dryness—not too dry, of course; but even this will be better than the saturation point on a saturated soil at this season some rats sour, and then the roots will not penetrate it. The only plants which are worth potting up later to the season are "Goraleum" and Pachista, and the last-named may, if protected, be left in the ground all winter. Do not let Palms get too dry; it is not well to go from one extreme to the other. Much good will be done by specking the foliage.

Outdoor Garden.

The Dahlias have had a pretty good time this season. At the time of writing my beds of Dahlias are very full of blossoms. It is a pity that a slight chill in the soil will spoil all this beauty. They will have a demand for cut flowers might find an advantage in growing some of the dwarf Pompones and Cactus varieties in pots. In some instances where I have seen this done the success has been very encouraging. The pots may be plunged out in summer. While Dahlias are always in demand for decoration. As soon as the frost breaks the growth of the plants in the beds, cut down the tops and dig up the plants, and after being cleaned, put away in a dry place, safe from frost. Hollyhock-outings should now be potted up in single pots and plunged in a cold pit or frame. Cuttings with me have been very successful: the losses have not been 5 per cent. Tuberos Begonias should be lifted out of the bed now. It is best to take them up before the frost injures them, though they are not at all delicate if not oozed to heat. The tubers may be kept in a sand in a dry jar. All the warmth required is to keep the plants above freezing-point, and also cover heavily with mats or straw when the frost sets in sharp. Geonias may be kept with almost as little trouble as Begonias, but do not let the frost bite them too hard before lifting them. Chrysanthemums against walls must be properly secured. It would be easy and not expensive to protect the plants on walls with tiffany or canvas when the frost comes, and Chrysanthemums play such an important part in our home-decoration work anything possible should be done to save them. Any Violets now yet put in frames or pots for winter should have attention at once. Only those plants which have been grown thickly are worth lifting.

Fruit Garden.

Frost root pruning. Young trees which are making too much growth may be lifted and replanted other to the same or other positions, or cut the leaves and roots, without waiting for them to fall. Wall-trees, such as Peaches and Apricots, may have the roots lifted and brought near the surface, if the character of the summer growth has been too gross. When a tree makes wood which is too strong to ripen properly, give attention to the roots by lifting in the case of young trees, and by working under the ball and cutting the downward roots in the case of old trees which cannot be managed in any other way. Continue to make preparations for planting young trees wherever there is room. There may be rather too many Apples and Peers in some gardens this year perhaps, but in a general way we are so much first-class fruit, especially our own as all market gardeners. In very old gardens the fruit-trees are often in a bad condition, and the thing is omitted, because the work, if properly done, means expedition. In such cases the old trees should be cut out, the borders removed, and a young tree planted. It may not be possible to do all in one, or even to two years, but, whatever is done, do it well, and then the result will be satisfactory. It is time now to gather all the late Peas and Apples. In most gardens I expect this work is completed, as the season is an early one, and the leaves are falling early. It is time all late Grapes were ripe now, even where fire-heat has not been much used. Keep all foliage in late vines clear of the glass, and promptly remove decaying berries, should any appear.

Vegetable Garden.

Aparagus seeds are out often now in autumn, but there is nothing lost, and perhaps something gained, by sowing as soon as the seeds are ripe. Green Beal is ordinarily always in demand for forcing, or, at least, it will be if it could be had. The variety which were out down in summer, potted up now will be useful for picking from during the first part of the winter. A supply of Green Tarragon and Chervil should also be thought of. All plants, such as Cardoons, Celery, Leeks, and salad plants, which require blanching before fit for use, should be closely watched now, as every very fine day taken advantage of. Onion-hills in heated houses intended for winter use should be kept high, and the plants should be kept to the stem to be kept within bounds. This planting is a disadvantage if the plants are to do mental work through the winter, and I never stop the leading shoots till they have travelled several feet up the rafters. It adds so much to the vigour of the plants if they are allowed to have their heads a little at the beginning. Sprinklings of fresh turfy compost are very desirable. It tends to keep the atmosphere pure and fresh, as well as affording support to the plants. Getting a vegetable garden for mixed pickles. These will include Cauliflowers, small Onions, Chilies, Radish-pods, &c. Lettuces and Endive which are full grown, or nearly so, must be protected in some way. Where there are spare frames the plants ought to be filled with balls of earth and planted therein, though they will be quite as safe some time yet outside if covered on frosty nights with dry Fern or old mats, or canvas laid over the plants will be sufficient for some time to come.

K Hoenar.

Work in the Town Garden.

The continued mild weather is extremely favourable to the development of autumn-flowering plants. The frequent frosts, too, have retarded things generally, in a remarkable manner, and gardeners that receive a fair amount of frost are looking better now than at any time during the season. The autumnal tints of the early or middle-flowering varieties are blooming splendidly, the plants

being dwarfed than usual, but the blossoms not so extra forward as might have been expected from the forcing character of the season. The Michaelmas Daisies, again, are flowering later than usual, but very finely, and with the stately and beautiful Pyrethrum uliginosum (by the way, I ever live of admiring this most elegant and graceful plant), Dahlias, Japanese Anemones, African and French Marigolds, and late plants of the Torch Lilies render the garden still as gay or gayer than ever. Begonias, too, are brighter and fuller of flower than ever. This cool, yet mild, moist, and showery weather is just what they fairly revel in, and only that so many of the plants and the seedlings of this year in particular received such a check from the scorching they had in August, the beds would indeed present a grand appearance. Cow-Whorrels are capital town plants, and a nice batch of the different shrubby varieties, grown in 5-inch or 6-inch pots, are invaluable for larding window-boxes, conservatory decoration, and so forth. For the former purpose use dwarf plants of the evergreen Euconymus in variety, Aucuba, Box, small Conifers, &c., are all very well, and, indeed, Iodipsea when there is nothing else to be had; but as long as it is possible I like to have at least a few flowers, it only in the front row, very dwarf Chrysanthemums of the large or medium kinds from cuttings inserted in July, or if not taken in August, will now be very useful, both for window-boxes and conservatory decoration. It is really surprising how well such plants bloom, considering the time and manner of propagation, but it is not uncommon for plants but little more than a foot in height, in 5-inch pots, to carry three or four flowers, each nearly as large as the top of the pot itself. Do not be too late in sowing the plants that can be grown in the ordinary way to a height of 2 feet or 3 feet only, but in the meantime these late-struck cuttings are extremely useful, and so are the out-down plants. It is somewhat surprising that this last-named method is not more generally adopted, by those whose houses are of low pitch particularly, but I think the drawback is that people are really afraid to cut their plants down to the necessary number. Whilst the roots of the greenhouse cow-whorl are thickly covered with clumbers these should now be raduced as far as possible, as the plants beneath will need all the light and air they can get for the next few months.

B. C. R.

THE COMING WEEK'S WORK.

Extracts from a garden diary from October 21st to October 23rd.

Rearranged one of the herbaceous borders. The plants have been several years without removal, and some have outgrown their positions, and a few, including several Phloxes which are superseded by better kinds of the same species, will not be again planted. Carnations will be more freely planted. The border has been cut well and matted, and in replanting groups varying in size will be planted instead of so many single plants. Half a dozen plants are more effective than one or two, but in the case of small-growing things more than half a dozen may be used to form a group—in fact, there need be no special number. We shall make the groups to fit the position. I dislike regular planting, and I also dislike straight, formal borders. These straight borders are a remnant of conventional gardening of the past. In the present case the border is not a formal one; it is backed up with shrubs, some of which jut out into the border. I find these recesses very effective when filled with such plants as White Lilies, Delphiniums, Hollyhocks, Tritomas, and other tall things which look well in masses. In front of these come masses of Anemone japonica, Phloxes, single and double Sun-flowers, Pyrethrum uliginosum, very effective in a large way. Just behind the Phloxes and Anemones these borders plant to flower are not disturbed. I always find late-blooming outsets are best transplanted in February, or later, and the early-flowering things in autumn, and no garden is furnished properly without Gaillardias, and the flowers are so valuable for cutting. A good batch in a border of Gaillardia grandiflora furnishes a handful of flowers whenever required. Laid down late Broccoli with heads to the north, hanging up the stems to the east, as in the most vulnerable parts. Yelch's Autumn Broccoli have been laid in cold pits, a few being left in the beds to take their chance. It takes a sharp frost to injure the hearts, so the leaves fold over closely. Finished earthing up Celery and Leeks. Tied up more Lettuces and Endive to come on in succession. We have a heap of dry Bracken to one of the sheds, and should frost set in the Bracken can be laid over the plants to a few minutes, and no harm will be done. This dry Bracken is found very useful for protecting Tra Roses, or to place over and around anything tender, or supposed to be tender, and it is one of the best protectors for cold pits in which tender plants are stored. The houses in which the Chrysanthemums are placed are still very freely ventilated, and being also kept closed at night. It is important that the leaves be kept healthy to the last, and the canes kept in a frosty, well-lit house with the frost just kept out. Manured and fringed a piece of land for planting out Brack-stocks for budding. It is always desirable to get them out as early in the season as possible. It is also very desirable to deal liberally with the stock, and there are always fewer deaths when the surface receives a liberal mulch of manure. Moved Cinerarias from cold pit to cool house. The early plants are now receiving liquid manure, weak, at every watering. Finished pruning Vines in early house. Finished the Seedling in a very useful Grape-vine lored, and it sets well, and does well in pots, but it is no use, the berries being too small, except for the first early crop. I think more might be done with Golden Queen where Muscats cannot be grown.

4843.—Colours of Violets.—Marie Louise (mauve-lavender-blue, with white eye), Comte de Brera (double white), Mme. Millet (tinted purple, shaded red), De Parmo (pale lavender-purple)—E. H. Marie Louise is one of the best of Violets, and a great favourite with all who care for these flowers. The colour is lavender-blue, with a white eye. Comte de Brera has white flowers, Mme. Millet is reddish-purple, and on the lavender-purple, De Parmo is a very purple-lavender. Very pleasing shade of colour.—C. T.

FERNS.

TASTEFUL FERNERIES.

By the exercise of a little taste in grouping suitable plants together with Ferns, the effect of both is considerably heightened—a fact that should not be lost sight of by all who intend to take in hand the arrangement of the plants in a fernery or conservatory in a natural and easy manner. This grouping is a practice heppily gaining ground, and one that, well carried out, cannot be too much commended. The rockery over the little pool in the fernery in our illustration is composed of a porous stone, and the Ferns and Mosses sow themselves in abundance all over it. The little fringe round the edge is almost entirely covered with self-sown plants, growing simply

in Sweden, his native country, as it is in almost all parts of Europe. I have, however, never been fortunate enough to see it wild in Ireland, although I have searched for it in its recorded habitats. Bernhardt, who was a professor of botany at Erlint, in Germany, removed it to the present genus early in the present century, because it had no special indusium or covering for the sori, which is a special feature in *Pteris*. It is, however, a lovely British Fern, having a slender, creeping rhizome, from which the fronds are produced. These fronds are deciduous, and the plant, although perfectly hardy, will not thrive in the open air where "Miss C." posted her letter from. I should the rather advise her to put the plant or plants into a well-drained pot and place the roots between some pieces of sandstone mixed with loam, and to

of ashes under the turf. If the soil is dug deeply over and made perfectly level, rolling it down quite firm before the turf is laid. Any irregularities of the ground will be so much more easily seen when the turf is laid than before. If "Daydon" decides to sow seed, the soil should be dug up roughly, allowing the weather to pulverise it thoroughly. Choose a dry day about the middle of March to finally level it and rake off any stones from the surface. Lawn Grass seed should be sown at the rate of 80 lb. to the acre; it is better to sow the seed thickly than otherwise. The early part of April is a good time to sow the seed, choosing, if possible, a day previous to a shower. A tonis-lawn made from freshly-cut turf, or even from seed, cannot be rolled too much, providing the weather is suitable.—S. P.

Rock pool in a fernery.

on the rock without soil, the roots of many hanging down in the water. C.

THE PARSLEY FERN (ALLOSORUS CRISPUS).

I CANNOT say why this plant received its English name, for certainly I never could see any resemblance to Parsley in it; but, nevertheless, it is one of the most beautiful plants that I know. I am asked the above question by "Emma Chadwick," who, it appears, has collected some plants in Devonshire, and brought them into the South of London, and she asks if it will grow in the open air, and she also enquires if there are any recorded varieties of it? Well, to all these questions I will commence with the last one first, and that is, I have not noticed any variation in the plant wherever I have seen it worth recording, and I have gathered it in Scotland at good elevations; also in Westmoreland and in Lenoashire, and in North Wales. This is the plant which Linnæus called *Pteris crispæ*, and it is found plentifully enough

keep this in a cold house, or a cool greenhouse; the fronds will soon die off, and the plant can be kept in a nice moist friable condition, which will preserve the slender rhizomes sound and well, and towards the end of April or the beginning of May the bright-green fronds will begin to appear, and charm every beholder; these in the sterile ones are somewhat spreading, but the fertile ones are erect, and the underside is wholly spermatiferous, having a slight difference. It does not like the sun, but delights in a moist shady place, but foul air or stagnant moisture must be avoided. J. J.

4063.—**Making a tennis-lawn.**—To make a lawn fit to play upon by sowing seed will require at least ten months from the present time before it is in a fit condition to use. By laying down turf it will be in good condition as early next year as it is required. Whether it is made with turf now or seed sown next April it should be drained if there is the slightest chance of water laying under it from heavy rains. A gravelly soil requires no addition in the shape

407.—**Campanulas in pots.**—Perhaps you are too impatient, as Campanulas, as a rule, are very easily grown, and a few slips taken off strike easily even in a window, blooming freely when the plants get a fair size. In cottage windows, especially, one sees them in perfection, and there is a large number of types—*C. Barrelieri*, *C. fragilis*, and others. *C. Barrelieri* is a drooping variety, like all the others for this purpose, and blooms with very great freedom, the flowers like little stars, and blue in colour. The shoots trail about delightfully, hanging down for some way over the pots or baskets as the case may be, and bearing blooms with remarkable freedom. It is on that account very suitable for suspended pots or baskets. *C. carpatia* is, I think, the species most commonly grown. The flowers are comparatively large, and of a blue colour in the type, but those of the variety *alba* are, as suggested by the name, white. I have also seen *C.*, or as it is more often called, *Platyodon grandiflorum*, very well grown in baskets, the large flowers almost hiding the growth. Its shoots, when the growth is robust, will sometimes hang down quite 2 feet, and make a brave show of colour. But the two best for windows or baskets are *C. isophylla* and the white form, the type being a blue-flowered kind. This is very easily grown, and is exceptionally free. A moderately light but rich soil should be used for Campanulas—say made up of loam, peat, and leaf-mould in equal portions, whilst a fair amount of sand should be added. You must not pot firmly, which is different to general practice, and abundance of water is required. It is quite a mistake to think that there are any difficulties to overcome, as from first to last their culture is not easy. During the winter the soil must be kept drier than in summer, and when the spring comes large plants may be divided and others potted on. Too much sun is hurtful. You need not have larger pots than 5-inch size, and let the shoots hang down gracefully all round.—C. T.

— All of this family thrive best in sandy loam, mixed with a third or fourth of leaf-mould and good drainage; if the loam is at all heavy or rough add a little peat and plenty of sand. Plants of the smaller growing kinds mentioned should be shaded from very hot sun in summer, and with free ventilation and careful watering they will grow and flower freely and well. They will be all right for the winter in the frame, if matted up well and kept dry in cold weather—that is, unless the frost is very severe, when they would be safer in the sunny window of a warm room.—E. C. R.

4056.—**Spring bulbs.**—Plunging the pots containing the bulbs in a bed of ashes means covering them with the fine sifted material, but ashes is not the best material for the purpose; Cocoa-nut-fibre answers best, or leaf-mould. They should be plunged out-of-doors, and the reason for this treatment is, that the bulbs should form roots before growth is made, and this treatment is best for the emission of roots. Ashes sometimes injure the growths. A cupboard heated by hot-water pipes is about the worst place that could be imagined to place newly potted bulbs; they would be forced into growth before roots could be formed, and would be drawn up apindly and wask in the extreme.—J. D. E.

4055.—**Making leaf-manure.**—The leaf of the Beech and Oak make much the best leaf-soil, and the present is an excellent time to commence operations. Collect leaves from the road-side, or get permission to do so in some plantation of these trees. Put the whole together and turn it a few times until they are thoroughly decayed. That from the road-side is best, because it secures a good bit of grit and horse droppings.—P. U.

TREES & SHRUBS.

SHRUBBY SPIRÆAS.

THE SPIRÆAS are beautiful flowering shrubs, all more or less of value in the garden. They are generally of graceful growth, moderately tall, though some are quite dwarf and bushy, and they flower profusely over a long season, often keeping up a scattered succession from summer until the end of autumn. Few shrubs are easier to grow, but in many gardens they are choked up with other things. Almost any soil will suffice, and it is easy to increase the stock by layers or suckers.

S. BUMALDA, a variety of *S. callosa*, represents well the dwarf and bushy section, and it has come more into note of late through the appearance of a very distinct and acceptable variety, in which the flowers are of a much richer colour than in the type. The typical *S. Bumalda* grows about 2 feet in height and is hardy, creating a pretty picture when planted in front of other shrubs to form a base, or in the shrubbery; not the choke-muddle arrangement usually seen, but where the several things are boldly grouped together. A mass of this form by itself makes also a happy feature, the flowers being of a rose colour, preceded in bold flat clusters, and when

A Shrubby Spiræa.

in full perfection very effective. The variety named Knapp Hill Crimson has flowers of an intense crimson colour, but in other respects resembles the parent, blooming over a long season. It is a sport. A shrub with flowers of such rich and decided colour is adapted for planting in distinct beds on the turf or against dark-leaved things to bring out the full depth of the clusters of crimson bloom. *S. Bumalda* is not one of the hardiest of the Spiræas, and it is important not to plant it in a very cold spot, or where the soil is poor.

S. CALLOSA or *S. japonica*, its synonym, is a lovely dwarf shrub, an indispensable Spiræa, and a native of Nepal and Japan. Fortunately it is not rare, and may be seen in all good gardens, where its graceful stems rising between 3 feet and 4 feet in height have a fine effect when enriched with the deep rose-coloured flowers. *S. callosa*, however, varies much, and amongst the several varieties occur some that thoroughly deserve attention. The white form—*alba*—is dwarf and makes a neat, shapely, and bushy shrub, the flowers white, and as in the type and all its forms, continue to appear for months until cut off by frosts. *Splendens* has flowers of richer colour, *semperflorens* (red), *atrosanguinea* (crimson), and *superba* (greenish-white), but this scarcely justifies mention. While writing of *S. callosa* we may refer to another dwarf species, *S. bella*, which bears some resemblance to *S.*

salicifolia, the Willow-leaved Spiræa; the stems are erect, the flowers rose-coloured, and produced in lax panicles during the months of May and June. It was introduced in 1820 from Nepal, and is quite hardy. The yellow colour of the decaying leafage makes it attractive in the autumn.

THE WHITE BEAM-TREE-LEAVED SPIRÆA (*S. arifolia*) is one of the finest of its race, and grows taller than any hitherto mentioned, rising to nearly 10 feet high in a good soil and position. It is now classed as a variety of *S. discolor*, and was introduced by Douglas in 1827 from North-West America. When once established the growth is free, dense, and graceful, heightened in beauty by a profusion of greenish-white flowers in July. Individually they are of little importance, but raised in the large clusters, which bend the shoots down with their weight, are showy and effective. Plants may be very readily propagated by layers. The English name was suggested by the leafage, which is not unlike that of the European Beam-tree (*Pyrus aria*). A shrub of this noble character, especially when in full bloom, is utterly spoiled if choked up in a common shrubbery. It should be certainly set off with a background of dark-leaved shrubs, but stand quite isolated, when it will grow to large and imposing dimensions. Then

it is one gains a correct idea of its beauty, the heavy clusters of flowers extending out in bold relief from the leafage. I like to see such shrubs as these isolated on the Grass, such as a bank near the waterside, where it has a fine appearance, and fortunately any free soil will suffice. The more vigorous Spiræas require a little attention in pruning from time to time to keep the shrubs within bounds, and prevent degeneration through an overcrowded mass of growth.

S. THUNBERGI is now fairly common, and its merits as a shrub for early forcing are recognised, the slender shoots covered with small white flowers being of great use for cutting. The shrub assumes a graceful form, and is the first of the Spiræas to bloom; but, apart from its flowers or value for forcing, *S. Thunbergi* is worth planting for its foliage alone, which in autumn assumes a splendid crimson colour, intensely rich, and remarkably uniform, every leaf being of this fine colour. Last autumn was, owing to the wet, comparatively unless weather, very poor for foliage effects, but the leaves of this Spiræa were as bright as in dry sunny seasons, and stood out conspicuously from the green foliage associated with it. Large clumps in the garden are worth looking at in the autumn, and have a delightful effect. It was introduced from Japan, and is perfectly hardy. Producing one of the best things we have received from that land of flowers.

S. HYPERICIFOLIA, or Italian May, as it is sometimes called, by reason of the white Hawthorn-like flowers, makes an attractive bushy plant, the growth pleasing and graceful. The stems are elegant and arch gracefully, and crowded with flowers in the summer season, when they have a charming effect in the garden. The type has been long in English gardens, as it was cultivated by Parkinson in 1640, whilst it may be used to form a hedge as well as a distinct specimen. It is easily raised by layers or suckers, and when allowed to grow in its own pleasing way is one of the most attractive of the Spiræas; but there are many varieties, some finer than the parent one, known in nurseries under various names.

S. REEVESIANA, or *S. ceatoniensis*, under which name it is also known, is sometimes classed as *S. lanceolata*, but the two are distinct; and both form attractive garden shrubs, the first named the finer of the two. *S. Reevesiana* grows about 3 feet in height, the flowers white, produced in fairly large clusters, and in such profusion as to make the shrub in the month of June a mass of white. It is also used for forcing in spring. There is a pretty double variety with white flowers. The true *lanceolata* of gardens is quite dwarf, and an attractive bush when smothered with the white bloom.

S. LINDEYANA is a noble species, remarkably distinct in appearance, and a fine garden shrub, producing a wealth of long pinnate foliage, delicate green in colour, and of charming grace, especially when set off by the bold plummy clusters of white flowers. It also blooms very late in the season—the month of August—when comparatively few trees and shrubs are in flower. Unfortunately, this beautiful Spiræa, being from the Himalayas, is not so hardy as many others, but in the suburbs of London I have seen it need well in a distinct bed on the surrounding edge of the lawn, where the soil is light and warm, and the position not exposed. A happy picture is thus produced, as its leafage is very elegant; and in more southern counties where well placed the shoots will rise to nearly 10 feet in height. It is also a good shrub to mix with other things for contrast if allowed to develop its own characteristic graceful habit.

THE PLUM-LEAVED SPIRÆA (*S. prunifolia*) is best represented by its double variety (*double-plee*), which is a lovely shrub when well grown; but, unfortunately, it is too often deprived of true beauty through neglect, by planting it anyhow amongst other things, and not permitting the growth to develop in its own characteristic way. It will thrive in ordinary soil, and although a native of sunny Japan, is very hardy, producing in the month of May a profusion of double white flowers, each like a charming little rosette. Like many of the other Spiræas, it remains in bloom over a long season, and may be made far better use of than crowded up in a common shrubbery, very often a mass of good things stifled to death through ignorant planting. V. C.

4700.—*Araucaria* (Monkey Puzzle).—A large quantity of fresh loam will certainly help your tree; but when this Piec commences to fall in its lower branches very little in the way of renovation can be done. I once had a large avenue of these under my care, and two of them having grown too close together to allow of a roadway between, the gate was placed on one side. Before deciding to do this several cart-loads of soil were removed from around one of the specimens and replaced with loam. The plant so treated grew away considerably beyond its fellow; but had it lost any of the lower branches they could not have been replaced. This noble, and yet formal plant, is not suited for many soils. It will grow in almost any for many years, but just as it is attaining noble dimensions the roots reach uncongential soils, and the lower branches go off rapidly. The first signs of this are evidenced by the needles turning rusty, and after that the plant is soon spoilt. A gravelly, and yet cool bottom, with a moist surface-soil, is what they luxuriate in. My plants ranged from 30 feet to 60 feet high.—P. U.

I have repeatedly pointed out that the Monkey Puzzle is one of the most unsatisfactory trees you can have in a small garden. It is entirely unsuitable for such a purpose, and invariably goes off in the way described. Even in such places as the Royal Gardens, Kew, where

the greatest care is taken of the specimens there, they are an utter failure, the lower branches dying off. I do not know whether they are there now, but formerly several Monkey Puzzles disfigured the beautiful park at Greenwich, and why they were planted in such a place, near to lovely groups of Thorns, is a mystery. The fact is, those responsible for the smaller gardens know nothing about trees, shrubs, and plants as a rule, and I should advise you to get rid of the Araucarias and put in some really beautiful things, as the Weigelas, and many other shrubs that have been recommended from time to time for small gardens. You cannot save your trees. Top-dressing of the best loam mixed with manure might give temporary benefit, but

Fig. 1. Common Shallot.

only temporary; the dead branches will not grow again, and half a Monkey Puzzle is not pretty. It is very well to point to such specimens as at Powderham Castle, in Kew, or Dropmore, the branches sweeping the turf, but the climate and position for them here are peculiarly suitable.—C. T.

— This is a most disappointing tree generally. In a few places it does well, mostly in the maritime districts. The tree requires plenty of moisture. This has been the likely cause of the bottom branches dying. If I had a tree that condition I should grub it up and plant something else more reliable.—E. H.

4657.—**Mistletoe**—There is no way to propagate the common Mistletoe other than by inserting the seed in a notch out in the bark. It is parasitical on the Apple-tree, and is also found on the common Poplar, also on the Hawthorn, the Mountain Ash, the Maple, and other trees; rarely upon the Oak. Some persons say that it is better to sow the seed on a natural crack or depression in the bark of the tree. The ripe fruit may be pressed into the parts most suitable with the fingers gently, so as to break up the viscid substance, but not to injure the seed. The white substance will be sufficient to keep the seed in its place, but birds may peck it off unless it is protected with wire netting or some similar material.—J. D. E.

4701.—**Hardy Azaleas**.—Hardy Azaleas, both the Gheet and Japanese varieties, will do very well where the soil is suitable. Very little, if any, pruning will be required. If much pruning is done there will be no blossoms for some time after. If the plants get lanky or straggling in habit, shorten back to put into shape, but otherwise the less pruning they have the better. Azaleas will not grow in a limestone soil. They succeed best in peaty land, but I have seen them do well without peat where there is plenty of vegetable matter and not much lime in the soil. The old Yellow Azalea pentica is one of the sweetest shrubs in the garden. I used to grow it largely for forcing, but of late years, since Azalea mollis has come so much into favour for forcing, pentica has fallen into the background.—E. H.

— Hardy Azaleas are perfectly hardy, as the name suggests, but you will spoil them if you prune. The charm of these shrubs is that they grow widespreading heads, the branches, so to speak, rising in tiers and loaded in the early days of June with their richly fragrant varied-coloured flowers. As you do not appear, from your note, to know much of this class, I may say that the hardy Azalea needs a good loamy or peaty soil. If the ground is heavy clay, for instance, you must have a peat bed, about 12 inches or 18 inches in depth, and give an occasional top-dressing in after years. They require some amount of shelter, especially from cold easterly winds, which injure greatly the

flowers, and spoiling the beauty of the shrub. Much advance has taken place with this group in recent years. The flowers individually are much larger, broader, and splendidly coloured, the shades of crimson and scarlet in particular, fiery masses, which light up the scenery with brilliant beauty. If you have a piece of woodland, sheltered from the east wind, and the soil is of proper description, there you may grow to perfection these shrubs, and no place is better for them than a clearing in woodland. The growth itself is very characteristic, the branches very leafy, and the foliage in autumn takes on splendid colours—crimson, bronzy-green, and chocolate. The season of flowering has been greatly prolonged by getting new late-blooming types, which carry on the period of flower-beauty until the end of July. The semi-double race is very charming, the trusses of bloom compact, and the individual flowers very pretty when out, whilst they have a delightful fragrance.—C. T.

THE KITCHEN GARDEN.

SHALLOTS AND GARLIC.

IN reply to queries, these plants are in every way so nearly related that cultural notes given in reference to the one may safely be taken as suitable for the other. Except in rare instances, however, their cultivation is somewhat neglected, a circumstance owing no doubt to the fact that there is not much demand for them. That, however, ought not to be accepted as a reason for neglecting their culture, for though we may be required to grow but few, it is surely worth while to grow those few well. The most suitable soil for them is a strong loam that has been manured the previous autumn and left to mellow under the winter's frost. This should be broken down smoothly with a rake early in February, and the bulbs should be planted in rows 15 inches from each other, and 9 inches apart in the row. No dibber should be used; the bulbs should be pressed into the ground with the fingers only. As soon as they begin to make roots it is necessary to give them another press down, or the roots will upheave the bulbs out of the ground. Beyond hoeing to keep the surface of the soil open, little else is the way of culture is needed to insure success. In order to obtain handsome produce, select the finest and best shaped bulbs for planting. As regards varieties, they are not numerous, and what there are vary but little in any respect except in colour and size, the quality of all being about alike, and all are no doubt more improved by constant selection of the finest for reproduction than by seed. The ordinary pale red-skinned (Fig. 1) is perhaps the most profitable kind to grow; it is certainly far more productive and hardier than the larger deep red-skinned Jersey variety (Fig. 2). There is also a good silver

Fig. 2.—Jersey Shallot.

skinned kind in cultivation, which from the appearance of the bulbs might easily be mistaken for Garlic, though it is somewhat longer than the bulb shown in Fig. 3, which is the common English variety of Garlic, and the only kind that need be grown. W.

Gathering Mushrooms.—Mushrooms should be pulled, not cut, giving a slight twist at the same time, so as to bring the stalk clear away. Pull all that can be found, and give the ground a light sprinkling of salt or the approach of rain after a good spell of dry weather.—B. C. R.

WINTER CUCUMBERS.

WHERE a supply of Cucumbers has to be maintained throughout the winter months, a certain amount of forethought is necessary. It must be remembered that Cucumbers are lovers of sunlight and long days, and under these conditions the plants grow and fruit freely enough, but not so at midwinter. At this time, unless the treatment is judiciously carried out, the plants will hardly grow, let alone bear fruit. Fitful supplies are often secured, but where Cucumbers are looked for, a regular supply is what should be aimed at. As is generally the case, the plants are spoiled at the first. They may have been planted all right and also grown in a suitable structure, but are ruined in the earlier stages and quite unable to bear the

Fig. 3.—Garlic.

strain which the dark days put upon them. That the plants may be in condition to fruit freely through the autumn and early winter months is no reason that they should be allowed to do so. At that time Cucumbers are not looked for in quantity, and this being so, it is of no use to let the plants bear the strain which these early crops undoubtedly put upon them. With the plants worn out, as it were, it matters little what after-treatment is bestowed upon them, as rarely are they able to recruit their strength to prove satisfactory. The want of Cucumbers is generally felt throughout the months of January and February, and particularly so during the latter month. I do not advise the same set of plants for the production of Cucumbers throughout the winter, as I like a set for producing fruits for the early part of the winter and another for the latter end. By having two sets, the first batch may be relied upon until the end of January, and then at this time the second batch will commence to bear and will continue through what is generally the worst season, as far as the production of winter Cucumbers is concerned. By relying upon two sets of plants, it must not be imagined that extra space is needed, as if room is scarce the same number of plants as is generally grown in one batch may be divided, and by arranging them in this manner a far greater number of fruits may be secured than relying exclusively upon one set and those planted early. For the successful production of winter Cucumbers

A SUITABLE STRUCTURE is of the utmost importance, as unless this is light, efficiently heated, and so forth, their culture would be attended with difficulty. A good heating surface is most desirable, so that a comparatively high and equable temperature can be easily kept up. To the want of this the failure of many winter Cucumbers may be traced. Before commencing operations it will be as well to consider the system under which they will be grown, whether in large pots or in prepared beds. Pot culture has its advantages and disadvantages, but personally I favour the planting out for the first or earliest batch and pot culture for the later—that is, where there is the convenience for carrying out the work in this way. When grown exclusively in pots it is most desirable that a comparatively high temperature be maintained, for unless the pots can be plunged so as to derive benefit from bottom-heat, the plants cannot make much headway. The pots being surrounded with warm fermenting material, so as to generate a bottom-heat of 80 degs., the roots are kept actively at work, and when this is so the plants remain healthy and do not wither. This certainly is the point where many fail with winter Cucumbers when grown in pots. As I have previously mentioned, the plants must be built up sturdily from the

first, and fruit should not be allowed to form until actually required, and then only sufficient should be reserved to keep a steady supply. Plants which may be raised now and duly planted out have not only time to form vigorous plants before the dull days arrive, but also to fruit heavily as well by the same time. Allowing the plants to produce these surplus fruits is only wasting their energies and weakening out before their time. It may appear waste to cut off the small fruits as they form, but this show is only fleeting, for sooner or later a collapse will come and the plants will refuse to grow, let alone produce fruit. The

RAISING OF THE PLANTS for what should constitute the first or main batch should take place so that they can be planted out some time during the month of September. By allowing them to become starved in small pots for the want of planting out, and perhaps also smothered up with other subjects, is only to court failure. It is best to raise the plants singly in 3-inch pots. Particular care should be taken that the small plants are kept to themselves, so that a class start may be made. The seeds after being sown should be plunged in a gentle bottom-heat, and directly the seedlings appear through the soil elevate them to the light. Nor must the little plants be allowed to waste water, which should be tepid. The soil for these winter fruiters must also be lighter than is generally used for the summer crop; but this, of course, will be gauged by the kind of loam at disposal. The soil I have to deal with being heavy, the roots work the more freely when it is used in the proportion of one half loam and one part each of pulverised horse-manure and leaf-soil, with pounded charcoal and old lime rubbish as correctives. With lighter soil to work with, use a third of loam. The formation of the beds, or rather mounds of soil the plants are to root in, will of course depend upon the formation of the structure and also the arrangement of the bottom-heat pipes. What is wanted is a genial root-run, with not to great a bulk of soil. The practice of using some fermenting material, either of well-worked stable litter, or, what is better, litter and leaves in equal proportions, for placing under the mounds over the bottom-heat pipes, is not favoured by some people. I do not think so, as I am certain that a layer to the depth of a foot, and this trodden firmly, forms an effective barrier to the dry heat which ascends from the bottom-heat pipes. Do not lay it direct on to the pipes, but over the usual layer of broken bricks which surrounds the pipes. The roots thereby work the more freely and are not subject to fluctuations of temperature. Over this litter the mounds should be placed, arranging them at least 3 feet apart. Whether turves will be needed to be placed underneath will, of course, depend upon circumstances. Certain it is that turves are of benefit where they can be used. A high and close temperature must be avoided, this forcing on the growth too much without that solidity so essential for successful after returns. What is wanted is a circulation of air, tempered more or less by artificial heat according to the weather. To attempt to gain this thus early in the season without a judicious application of artificial heat will only result in attacks of mildew.

The growing must be trained thinly, the main laterals being thinly disposed. The secondary shoots should be stopped at the second joint, or what is known as one joint beyond the fruit, whether fruit is expected to form or not, as this of course may be removed if not wanted. The shoots must be kept judiciously thinned out, and the larger leaves should also be removed to let in the requisite amount of light. Nor must the roots have less attention, as the soil must be kept at an even degree of moisture, taking the precaution, however, that the soil is moistened through. The roots must be kept actively at work also by judicious top-dressing and feeding up with clarified liquid-manure. The application of liquid-manure may be easily overdone, however, during midwinter. The growth at this time is at its lowest ebb, and applying liquid-manure too freely is apt to sour the soil, with the result that the plants quickly take on a sickly appearance. With a good heating surface command the temperature may be easily kept up during the night to 65 degs. with an extra 5 degs. on mild nights, allowing, of course, the

natural rise by day. For the secondary batch the early part of November is quite time enough for planting. As I have previously remarked, this batch is best grown in large pots, and by being plunged in warm leaves, or fermenting litter and leaves mixed, satisfactory crops will be secured. Plants such as these may often be produced when grown in a stove, always taking the precaution to keep them away from insect-infected plants, especially those subject to mealy bug. A.

ORCHIDS.

ODONTOGLOSSUMS.

In answer to "Msc.," I should advise him to get all those of *O. crispum* section, *O. Intepurpureum*, and *O. Pescatorei* with other similar kinds at once, if they require it, but if not I would take away any decayed or old soil from them and renew with fresh. I have noticed that in some places this summer these plants have been somewhat punished by the very hot season, and that they have hardly been able to maintain themselves. To all those people I have recommended this use of raised beds, which have the effect of maintaining a very much cooler atmosphere. With those persons not provided with a north house it has been difficult to keep them, but in such circumstances I have advised these raised beds to be permanently fixed, and to have another one to roll up and down to cover it; besides this, the house to be kept in a nice moist condition. The *Odontoglossum* will now begin to grow and move along comfortably in congenial weather, but I do not refer to *O. citreum* or any of this section, which should now be resting and be kept quite dry. For this plant coming from a somewhat lower elevation, requires this to cause it to flower, and it should be potted or re-surfaced in the spring when the spikes begin to show, using good peat-fibre and chopped Sphagnum Moss in about equal parts. MATT BRAMBLE.

THE SIAMESE SACCALAHUM (S. CELESTIS).

THIS beautiful plant, when I first saw it blooming with Mr. Cobb, of Sydenham, a few years ago, completely took me aback, it looked so exceedingly elegant, and its light-blue colour, which is so rare amongst Orchids, was so charming. Now the forms sent by "J. Mendoc" are just the two extremes which I have seen the species before break into. This is an Orchid of which we know but very little, and I think the only plants that have reached this country have come home through M. Roebelin, and in his letter to Mr. Shuttleworth he said: "The plants grew upon the bare trees in the Rice-fields of Siam, which had been left in the clearing of the ground for the planting of Rice." Now, this at once gives an idea of the requirements of the species in question—great heat and abundance of moisture in the atmosphere. I do not think it is a species that has been imported during the past year or two, and I should advise Mr. Sandor or someone else to send us some more plants home, in order to keep such a fine Orchid before the eyes of the amateur Orchid-lovers. In doing so there can be little doubt but some other fine things are also to be found, and so we should obtain a fresh stimulant to cultivate warm-house Orchids, for this one is so beautiful that it is beyond all praise. It belongs to the section having erect spikes of bloom, which are produced freely, two of them upon a single stem, bearing from thirty to fifty blossoms, which are white at the base, tipped with a bright, pure blue, the lip also being tipped with the same shade of blue, this in some varieties being a light blue, but in others darker, but beautiful in any shade. The plant is an erect grower, producing its leaves in a two-ranked manner; these being about 6 inches long, which are keeled, thick, and fleshy in texture, with præmose ends, and deep-green in colour. The flower-spikes arise from the base of the leaves, erect, and about 9 inches in height. The spike from which the flowers now before me were gathered is not much more than 6 inches high, but it does sometimes attain to a greater length; and I have measured the old spikes of some of the imported plants 10 inches in length, so that my friend may look forward to a

crease of pleasure from this Orchid. It should be grown in a basket and hung up near the roof-glass, so as to have the sun and light, but not exposed to the hottest sun, but slightly shaded during the fiercest of its rays, in order to keep the plants of a good colour, and to prevent its being burned. The basket should be well drained, for as the plant requires a great quantity of water during the season it is quite necessary that this should run away freely. The plant must not even be allowed to become very dry, or the chances are the leaves would shrivel, turn yellow, and fall away; and they cannot well be spared. MATT BRAMBLE.

4662.—**Sawdust as a manure.**—That sawdust does not very readily decompose is not (except where the soil is already surcharged with organic matter) a material objection to its use as a manure. It should be remembered that in the most fertile soils the proportion of matter directly available to the roots of plants is but a small fraction of the whole. The beneficial action of by far the greater part of the organic matter contained in the soil is purely mechanical. In stiff lands sawdust, even in its undecomposed state, acts beneficially by dividing and lightening the soil, and in both stiff and light lands, when it is decomposed, it increases the power of the soil for absorbing and retaining heat and moisture. In sandy soils the power of decomposed organic matter to hold back soluble fertilizing material applied to the soil is a peculiarly valuable property. I am fully aware that many cultivators have a strong objection to the using of sawdust as a manure; but the fact should not be lost sight of that almost all vegetable matter contains woody fibre, the essential constituent of sawdust. It is found in the leaf-stem, the midrib and the veins of leaves, and even in flowers and fruit. The peculiar mechanical action of leaf-mould as a potting material is due in great part to its partially decomposed woody fibre.—L. C. K.

4616.—**Packing Lilliums.**—You might take the bulbs up and dry them off. Thousands of Lily bulbs are annually treated in this way in this country, and by the Dutch and Japao trade growers. The bulbs are not found to suffer any serious loss of vitality when dried off, but I should never treat them in this way unless circumstances compelled me to do so. It is not natural for Lilies to lose all their roots when at rest, and they certainly stand more vigorously when the roots are preserved. I should lift them carefully, and pack in boxes in damp Cocoa-nut-fibre or Moss, in which they may remain through the winter. The common white Lily must not be dried off, being now in growth.—J. C. Hyatt.

4692.—**Mealy bug.**—The mealy bug is a very difficult insect to get rid of when once it gets into a vine. As soon as the crop of Grapes and the leaves are off, the stems of the Vines and the roots should be scraped with a blunt knife to get off any loose bark. They should then be thoroughly cleaned with a stiff brush, and painted over with the following mixture: 2 lb. of flowers of sulphur, 2 lb. of soft-soap, and a wineglassful of turpentine. Should be made into a paste with a little water. Boil 1 lb. of Tobacco and 6 quarts of water in a clean vessel for an hour, strain it, and mix it with the paste with enough water to make 5 gals. The woodwork of the house should be washed with the same mixture, or dress the stems and rods with three parts of clay, one part of tar, mixed with enough water to make a paint.—G. S. S.

4676.—**Carnations in a smoky district.**—The Carnation is a plant that will do better than most in smoky districts. No better arrangement for the culture of the plants could be made than that suggested. The plants will do very well in the frames all through the winter, and should be planted in flower-pots in March, placing them out-of-doors until the pots are ready to burst open, when they may be placed in the house with ample ventilation. Roses would do well treated in the same way, but they are not so well adapted for a smoky district as the Carnations; in fact, the Rose likes a pure air, and generally pins away in the neighbourhood of large smoky towns.—A. D. CAMPAIGN

BEYTON GRANGE.

FROM Bury St. Edmunds to Beyten le about six miles, and all who pass that way will see Beyten Grange, for the charming house and pretty garden, so faithfully shown in the engraving, stand by the roadside. It is the residence of Mr. Le Henp Cockeage, and though it is little more than a roadside villa, yet it possesses a beautiful garden, which far exceeds what is generally seen in such places. The house nestles down in front of some tall silvery Willows. Its walls are entirely hidden with Ivy, whilst Roses and Clematises scramble over the porch, and our native large White Convolvulus becomes a beautiful thing as it climbs up the face of the Ivy and its flowers peer out from the dark green leaves. When I saw it last summer (1892) window-boxes filled with flowers varied the Ivy mantle upon the wall. A border round the house was filled chiefly with Margurites, and well they looked in broad masses, with a foreground of Ivy-leaved Pelargoniums and the grey-leaved Cineraria maritima, whilst a few little masses of deep blue Lobelia gave variety of colour. The arches, which look so beautiful in the picture, lose none of their charm by an inspection. Gloire de Dijon Roses and Clematises are intermingled in wild, free masses, forming huge wreaths of foliage and flower. The flower-beds are all well filled with bedding plants of the usual type, but well grown and abundantly flowered. These beds, however, were not a repetition of the usual scarlet, yellow, and blue. They exhibited a much variety as is obtainable from this system. The old Gazania splendens creeping about the ground and blended with Blue Lobelia, the Purple Verbena venosa associated with Flower of Spring Pelargonium, the curious Salvia Horminum with coloured bracts extending out from and above dense tufts of the dwarf Tagetes, a scented-leaved Pelargonium, and the cool grey-leaved Cineraria toned down the bright masses of other Pelargonium; these were some of the better and less common charms of this bedding system. They were simple harmonious combinations

whose beauty was not lost in the complexity of pattern arrangement. But with all this array of flowers, gorgeous in their summer dress, I missed the fine hardy plants which would look well in some of these beds, plants which by scent and fine form appeal to other senses besides that of sight alone, plants which when brought to our gardens and planted remain there and increase in interest, size, and beauty as each season rolls round. There may be visionary delights in gazing upon these masses of colour on a warm summer's day, but in the midst of the feast there will crop up memories of the past. How often does an early frost come and make the garden here! One frost, perhaps, will be succeeded by a month or six weeks of fine weather, in which such a garden has no enjoyment to offer. This should not be so, because selected hardy plants, cultivated as are the bedders, will flower as freely and continuously. It is only when the severer frosts come that they cease to bloom. There is abundant evidence at Beyten Grange of the owner's desire, but it is to be hoped that present realisations, though good, will now content, but lead to the creation of something better and of a more permanent character. —R.

HOUSE & WINDOW GARDENING.

POTTING UP PLANTS FOR A WINDOW.

JUST before the first frosts arrive our gardens often contain many handsome plants well set with buds, which will certainly never open in the cold blasts of autumn. Amongst these there may be Margerites, both white and yellow, which have grown into neat little bushes in the borders and are now in full bloom. Carnations, too, which have been late in forming buds from the drought or being put out late in the season are now throwing up tall spikes of bloom, destined to destruction unless taken into shelter in time. Abutilons, Brugmansias, and other semi-tropical specimen plants will have grown too large for a window; but yet there are plenty of smaller plants in most gardens which might be potted up with advantage and used for winter decoration during the dull days. Chrysanthemums, for instance, where their growth is not too straggling, will flower much better indoors than out in most seasons, and these can be raised without difficulty if the following plan can be adopted about ten days

at hand to destroy the first comers of these insect pests, and an occasional syringing out-of-doors or watering overhead with a rosed pot will be found useful to preserve the foliage of Chrysanthemums in full beauty. Carnations, and some varieties of Margurites, are not so troublesome with regard to blights, while others are especially subject to thrip and green-fly. Prevention is better than cure in this matter as well as in everything else, and the constant use of a little clean soap and water, with sharp inspection of the tender shoots and the backs of the leaves, will save a vast amount of trouble, and preserve the plants in full vigour. L. R.

4671. — Window plants. — The plants named would keep better in a spare room than in a frame, unless the frame could be covered during frosty weather with an old carpet or plenty of straw, which would have to be removed in mild weather, as plenty of air is necessary. But they are apt to damp off in a frame if too much rain reaches them; also there is a danger from mildew settling on dead leaves or other matter, which must be guarded against by picking off all decaying parts and keeping

all sweet. The plants if put in the frame should stand on a layer of fine, dry ashes, and the pots should be completely covered with the same material. They will then need but little water, only putting them out to a good mild rain occasionally; the lights being raised, however, daily from ten to three o'clock by means of bricks in wet weather (so as to keep the rain off the plants), and thrown right back in fine, mild weather; closed completely only during frost, when the glass must be covered as mentioned above. If the plants are taken into the house, a sunny spare room, without a fire (except in frost) will suit them well, and they should have all the air and light possible, except during a sharp frost. When this occurs, the plants may be lifted from the window and placed in the warmest corner of the room, covered with newspapers, two or three layers thick, which will keep out all but the severe frost, when they could be put into

OUR READERS' ILLUSTRATIONS: Beyton Grange, Bury St. Edmunds. Engraved for GARDENING ILLUSTRATED from a photograph sent by Mr. Edward Le Henp Cockeage.

before taking the plants up, their roots should be cut round at a sufficient distance from the stem to make the balls fit the pots into which they are to go; a small sharp spade being used for this purpose perpendicularly into the soil without disturbing it further. Directly this is done, the plants to be raised should have a good soaking, either with water, or, still better, liquid-manure or soot-water; this will stimulate the cut roots, and induce them to throw out a mass of small rootlets at once. When the plant is raised, a week or two later on, the ball of earth with these rootlets should be kept intact and merely placed in a drained pot, with a little rich soil to fill the interstices. If the plants are allowed to stand on a bed of ashes, sheltered from the sunshine by a north wall, for a few days after they are potted up, and well supplied with water, they will not feel the check, and will continue to produce their blossoms as though still in the border, when they can be placed in a sunny window, giving them all the air and light which they can have. Chrysanthemums do best in a room without a fire, as they object to dry heat, and are apt to be attacked by black and green-fly if exposed to it. A piece of sponge with a basin of warm soap and water should be always

the kitchen window or into the sitting-room for a few days. All dead and dying leaves and stems should be removed at once from them, and they will be the better for a little good top-dressing (of leaf-mould, sand, and loam), digging on the surface soil to the depth of an inch or so, and replacing it with sweet, fresh compost. Watering must be done thoroughly, when at all, enough lukewarm water being given to run through the pot, and the saucers being emptied an hour afterwards; but no water should be given again until the upper soil is dry enough to leave no stain on the finger placed on it. Each individual plant differs in its needs, according as it has strong roots, or is making growth; all hard-and-fast rules, such as water once a week or twice a week, are therefore dangerous; and the owner should look through the plants daily to supply that which is really needed, and that only. —L. R.

4666. — Wooden labels. — Wipe them over with a rag just moistened with thick white paint, rubbing it in well, and leaving very little on. Write on them with ball pen, and the letters will last as long as the wood. —B. C. R. Quicklime dissolved in water, and whilst hot stirred up with a little oil, makes a good mixture for painting wooden labels. When dry you can write upon them with

CABANA CHAMPAGNE

INDOOR PLANTS.

4607.—Plants for a cold greenhouse.—*Chrysanthemums* which have been grown without high feeding will do fairly well in the unheated greenhouse if the hoome can be kept from damp, which is mainly a question of careful watering and ventilation. When cold weather sets in it should be possible to improvise a cover for the cold greenhouse, which could be rolled up on fine days. If this were done, many plants might be grown without artificial heat, including *Fuchsias*, *Myrtles*, *Camellias*, *Tuberous Begonias*, *Genistas*, and *Coronilla glauca*. There are many beautiful things among choice hardy plants, such as *Tree-Peonies*, *Indian Rhododendrons* and their hybrids, *Dentzia gracilis*, *Ghent* and *Japanese Azaleas*, *Carnations*, *Laurustines*, *Jasminum nudiflorum*, *Fatmagium grande*, *New Zealand Flax*, one or two of the hardy *Fan Palms* (*Chamereps*), *Dracena indivisa*. There are plenty of early-flowering hardy plants that will be as beautiful and interesting under glass as the common greenhouse plants, with which such houses are usually filled.—E. H.

—Some capital plants for an unheated structure are *Spirea japonica* and *S. palmata*, *Dentzia gracilis*, *Dielytra spectabilis*, *Hydrangea paniculata grandiflora*, as well as the common kinds, *Myrtles*, *Azalea mollis* var., *Primula Sieboldi*, *P. obconica*, *P. japonica*, and others, *Campanulas*, such as *C. pyramidalis* (hine and white), *P. fragilis*, &c., choice *Auriculas* and *Carnations*, *Roses* in *Laurustinus*, and for winter flowering *Christmas Roses*, *Laurustinus*, *Violets*, the hardy *Cyclamens* (*C. com.*, *C. europaeum*, *C. Atkinii*, &c.), and others. Even the ordinary Chinese *Primroses*, single and double, are very nearly hardy when sown in a greenhouse or frame in May, and grown without any fire-heat whatever, though they will not bloom much until the days begin to lengthen. The Persian *Cyclamens* also are not injured by a few degrees of frost, if hardily reared throughout. Even *Camellias* may be managed well in an unheated house, especially if by means of thick coverings over the roof in severe frost only a few degrees gain entrance. Another most useful class of plants for such a purpose are the shrubby *Calceolarias*, of which there are several very pretty varieties, all very nearly hardy. *Tuberous Begonias* may be wintered in a kitchen cupboard, and bloomed here during the summer; and, in fact, there is no end to the possibilities of a sunny and well-managed cold glass structure.—B. C. R.

4631.—Lemon-scented Verbena.—It is rather too late in the year to strike cuttings of the Lemon-scented Verbena. It is deciduous and should rest in winter. The plants ought to be cut back a little in the spring, and when the young shoots have grown 2 inches or 3 inches, some of them may be taken off with heels attached, and they will strike very freely in a hot bed, or in a little bottom-heat in a forcing-house.—J. D. E.

—This plant cannot be propagated by cuttings without the aid of surrounding glass to keep the atmosphere quite moist for the leaves, while the roots are in progress. But it is easy to strike a cutting of the young shoots (in a window, even) if covered by a tumbler or bell-glass, which should be taken off, and wiped dry every morning, replacing it, and keeping the soil quite moist. The compost used should be nearly half sand, with ordinary loam for the other half, and good drainage; when the little plant begins to grow, the sheltering glass may be gradually removed, until the Verbena has become independent of it, after which it can be repotted (giving a rather richer soil), or put into a warm corner out-of-doors, where it will grow luxuriantly during the summer. In Devonshire these plants usually survive the winter in the open air, doing especially well, if the collar (i.e., the part of the plant which enters the ground) be well covered with dry ashes in autumn. In colder districts the *Aloysia* should be potted up and taken indoors in September. It is now very late for striking cuttings; the summer is the proper time, but it may still be tried.—I. L. R.

4635.—*Gloriosa superba*.—The essential conditions of temperature can be obtained, the *Gloriosa* is an easily-grown plant. The bulbs are now in their resting period, and remain

quite dormant during the winter. They are also rather slow to start into growth in the spring; it is generally March or April before any growth is made. They might start more readily in a bottom-heat, but this is not really necessary. The bulbs should be repotted early in the year before any roots are formed; the soil should be just moist enough to start them in a Greenhouse or plant-stove. It is a hot-house plant, and good specimens will grow to a height of 6 feet or more, producing abundantly its rich orange and red blossoms. It is liable to the attacks of insect pests, particularly thrips; but it can be kept clean by daily syringings when in growth. In autumn, when the plant is at rest, no water is needed until the spring, when growth begins again. The flowers are striking and handsome, being also freely produced.—J. D. E.

4644.—*Freesias*.—The leaves of *Freesias* should not be long and drooping at this time of the year. They have been grown in the vinery at too great a distance from the glass roof. When the bulbs were potted in August, the flower-pots containing them should be plunged over the rims out-of-doors, and as soon as the plants have pushed out of the ground an inch or so, they ought to be removed to a cold frame, and the lights must be removed altogether when the weather is fine. All such plants as these require much light and air to keep them in good condition.—J. D. E.

4652.—*Nerine Fothergillii*.—This species requires much the same treatment as the Guernsey Lily (*N. sarniensis*). Repot the plants just before the season of growth in loam, leaf-mould, and sand. They may be repotted once in two years. During the growing period they do well in a brick-pit with a little bottom-heat; the season of growth is after blooming. They must be freely watered at that time, and be gradually dried off as the resting period draws near. When at rest give no water.—J. D. E.

4655.—Treatment of a *Bermuda Lily*.—It is not easy to give the exact reason why the flower-stalks of this Lily went blind the second year. It is not difficult to manage, and the bulbs will flower very well a second year or more after being imported. If the plants made good growth and the heil is sound it might do very well another year. They will flower twice in one season, and do well the next year. The bulb has been potted at the right time, and it should be plunged over the rim of the pot in Cocoa-nut-fibre-refuse, or some such material, out-of-doors, until the plants have made some growth.—J. D. E.

4617.—Treatment of *Camellias*.—You do not mention what colour your small leaves of these plants change; if yellow, while the remainder keep green and healthy, probably it is only that those changing are becoming ripe previous to falling off. All foliage dies more or less at some period of the year. Should they be a healthy pink, it is because they are too young to put on the deep and glossy green that old foliage possesses when in full health. Your plants are doubtless removed under cover now; if not, lose no time in doing so. Look to the drainage, remedying this if defective. A few waterings with soft water will help them very much, or you may place a layer of coal-seeb on the surface, at the rate of half an inch to an 8-inch pot; but great care will be needed in watering afterwards, because the surface will present much the same appearance, wet or dry.—P. U.

4642.—Flowers for Christmas church decoration.—Roman *Hyoisinth* potted at once, three bulbs in a 4-inch pot, or six in one 3½-inch diameter, plunged in ashes or Cocoa-nut-fibre-refuse in a cold frame, or out-of-doors where they will not get too much rain, should flower at Christmas, if a gentle heat can be given them afterwards. The bulbs should remain in the plunging material for six weeks, sufficient time to admit of the bulbs filling the pots with roots. *Arum Lilies* are much appreciated for Christmas decoration. To have them in flower a little warmth is necessary, and the plants must be strong, supplying the roots freely with tepid liquid manure. *Dentzia gracilis* prepared for forcing is a useful Christmas flowering plant, and so are white-flowered *Azaleas*; but these are rather expensive, and must have been prepared for the purpose of being encouraged to make early growth in the spring, so that their buds are

plump by this time. Double White *Primulas* give a quantity of flower. A light airy position in the greenhouse, where a temperature not less than 45 degs. by night and a rise of 10 degs. by day can be maintained. *Christmas Roses* are easily forced into flower, they require so little heat. Pot up strong clumps at once in moderately rich soil, giving them the protection of a greenhouse for the present. If there are any doubts of their being expended a little heat will hasten them on quickly. *Helleborus niger* is the best variety. *Bouvardias* Alfred Neuner, double white, *Vreelandia*, and *Jasminoides* are all free-flowering subjects if given a temperature similar to that for the Double *Primulas*.—S. P.

4602.—Treatment of *Aspidistras*.—The *Aspidistra* or "Milk Palm" is one of the easiest plants to grow, ordinary greenhouse treatment suiting it admirably, the chief fault with amateurs being that they do not sponge or syringe the foliage often enough. Leaf-soil and peat in equal proportions, with a dash of sharp sand and a little broken charcoal, make a good compost. Efficient drainage is of great importance, as the plants enjoy plenty of water without fear of stagnation.—P. U.

—Too rich a soil, too much root room, and not enough sun are the chief causes why the leaves come green instead of variegated. Good peat and sand are quite rich enough for a potting compost for these plants, and when large specimens are wanted, pans about 7 inches deep should be used in preference to pots, or else the pots should be half filled with rocks. In the winter the plants will stand full exposure to the light if they are placed on a greenhouse stage, but in the summer they require the glass to be shaded.—J. O. C.

4837.—Heating a small greenhouse.—This perplexed correspondent may very easily overcome his many difficulties with the Loughborough boiler by obtaining an automatic damper. Prior to adopting this ingenious arrangement I also experienced difficulties with my boiler. After several months' use I am most heartily recommend the automatic damper to your correspondent, and can assure him that in the end he will find it reduce the outlay for fuel, maintain an even temperature in his greenhouse, and will keep the fire in for at least twelve hours.—D. B. CRANE.

4706—"Geranium" in winter.—Very strong plants will generally survive if tied in bundles and hung up in a cellar or similar place, but not too dry, to which little or no frost can penetrate. A much safer and better plan, however, is to take the plants up, before they are injured by frost, cutting back all the strong shoots to about 3 inches of stem, and clipping the ends in time to prevent decay. Then either place them singly in small (3½-inch or 4-inch) pots, shortening the long, coarse roots moderately, and using some fresh sandy soil, made fairly firm, and with good drainage; or else pack them closely in deepish boxes, each with some rough ashes or broken bricks in the bottom for drainage, working some of the same soil as before in among the roots, and making all firm. In either case give them a good watering in (with tepid water), let them dry moderately (if possible out-of-doors in the sun), and remove to a sunny window in a warm room for the winter. Give water only so as to keep the soil from becoming very dry and the plants from shrivelling, then only or chiefly in the forenoon of fine mild days, and most of them will survive and begin to grow again in the spring. If kept fairly dry and cool they will do nearly as well away from the light as in the window, and a few degrees of frost will do no great harm, though this is better avoided. In the spring, when they begin to grow again, give a little more water, pot singly, harden off in May, and plant them out again early in June. Such old stumps usually bloom splendidly.—B. C. R.

4840.—Keeping *Fuchsias* through the winter.—*Fuchsias* may be kept in the cellar if the growth is well ripened without cutting down. They should be well hardened by exposure before storing them away.—E. H.

—Certainly; but do not cut down the plants as you suggest. If pruned at all, remove the tops and small spray only. See that they do not become very dry at the roots, or the plants will shrivel and die.—B. C. R.

—It is not necessary or wise to cut the plants down to the roots to keep them through winter. Prune off a few of the outside straggling shoots so that they take up less room. These should be laid on their sides, either in a cool place or in a little iron frost will preserve them well enough.—S. F.

OUTDOOR PLANTS.

EVENING PRIMROSES.

THE *Oenotheras* or Evening Primroses form a large and very important section of our summer and autumn-blooming plants. They are mostly confined to North America, the chief exception being *O. taraxacifolia*, which is Chilian. All are perfectly hardy and as a rule easily grown. From early April until the autumn frosts set in some few of the species will be found in flower, almost dazzling the eye with their masses of rich golden-yellow, white, or rose-tinted blossoms. Their fault, if fault it be, is, as their name implies, that of opening their beautiful flowers chiefly in the evening. This, however, is by no means general, and some of them will be found that open their dazzling flowers during the day. The annual species, with the exception of *O. odorata* and its varieties, may well be dispensed with from the flower garden. They are often troublesome from self-sown seeds, and none of them can be compared with the perennials and biennials for beauty of form or colour. The place for the robust grower will be the wild garden and the shrubbery border. *O. Lamarckiana* is perhaps the most useful for this purpose. The only thing to guard against is the numerous seedlings, which should be thinned out regularly during late autumn or spring to 2 feet or 3 feet apart. Those like *speciosa*, *linearis*, and *fruticosa* will be found admirably adapted for the mixed border, and those of the *marginata* section make an interesting and charming display on the rockery, for which, indeed, they are peculiarly adapted. Amongst the species not detailed below, and which will be found valuable either for the rock garden or mixed border, the following may be noted: *O. ohrysantha* (yellow); *O. rosea* (rose); *O. punilla* (yellow); *O. riparia* (yellow); *O. sinuata* (pale yellow, turning to rose); *O. Drummondii* (white and yellow); *O. tenella* (an annual, purple); *O. densiflora* (annual, purple); *bistorta*, &c.

O. albicaulis.—This is little more than a biennial—at any rate, it has proved with us a very short-lived plant, though well worth the trouble of propagating annually by seeds. Dr. Gray says it is perennial, which we much doubt. The stems are erect, about 1 foot or 1½ feet high, branched on the upper portion of the stem, smooth, shining, and usually of a greyish-white. The leaves are narrow, entire or irregularly toothed. The flowers are produced in the axils of the upper leaves, white, becoming pink with age. It is a native of the barrens along the Plateau, Saskatchewan, &c., and is a useful species for the rockery, where it flowers in early summer.

O. BIENNIS is not much grown as a garden plant, although few biennials are better suited for naturalising in woods and shrubberies. Its variety *grandiflora*, better known perhaps as *Lamarckiana*, is the one usually seen in flower in our borders. The whole plant is more robust, and the flowers are larger and much finer than those of the type. It is an excellent border plant, singularly beautiful in large masses, and well adapted for the wild garden or shrubbery, as it seeds itself in the greatest abundance. It is easily increased by seed, which should be sown annually to keep up the stock. Throughout North America, flowering June to August or September.

O. CASPITOSA, an illustration of which accompanies these notes, belongs to the acaulescent group. It is perfectly hardy, very easily managed, and a remarkably beautiful free-flowering species. The flowers are large, white, turning to a delicate rose colour with age. It is found on the clayey calcareous slopes of the slate hills of Upper Platte, but rare. It is most abundant on the Missouri along with *Astragalus galeoides*, flowering in July. It is a very distinct and beautiful species nearly allied to *O. acaulis*, and about which there seems to be some confusion. It is well figured in the *Botanical Magazine*, tab. 1393, under this name. It is the *O. scapigera* of Pursh Fl. and *Pachylophus Nuttelli* of Spach. In the "Botany of

California" it is described as above, but *O. marginata* (*Botanical Magazine*, tab. 5828) is given as a synonym, to us a totally distinct plant in every way, as may readily be seen by a comparison of living plants or plates.

O. FRUTICOSA.—This species and its two or three varieties are among the very finest of our hardy herbaceous perennials. They rarely exceed 2½ feet or 3 feet in height, and all through the summer and autumn bear a profusion of the most delightful golden-yellow blossoms. *O. glauca*, often given as occurring in gardens, is said to be nearly allied to the above. It is so near that I have never been able to make it out. Taking the character laid down by Dr. Asa Gray, *O. fruticosa* is hairy, white, and *O. glauca* is glabrous. The variety *Fraseri* which belongs to *glauca* is represented in gardens by a taller form of *O. fruticosa*. So hardy is *O. fruticosa* and its varieties, that they go on flowering after the first frosts in autumn, and even our hardest winter leaves them untouched. It well repays cultivation, and the clumps should be divided every second year and planted into good rich soil. It may also be raised from seeds, which ripen freely. It is a native of dry barren soil throughout North America, and flowers with us from June until the frosts appear in autumn.

O. LINEARIS.—A slender growing perennial, found abundantly in dry, sandy places from

Evening Primrose (*Oenothera caespitosa*).

Virginia to Florida, North Carolina, &c., flowering in our borders from April until July. It rarely exceeds a foot or so in height. The flowers, which are comparatively large, are of a soft pale yellow and fragrant, more so than in any of the other species we have grown. This will be found a useful plant for the rock garden, where in rich free soil it forms fine tufts.

O. MARGINATA, known also in gardens as *O. eximia*, belongs to the acaulescent section, and is admirably suited for the rockery or the front row of the mixed border. Even when luxuriant it rarely exceeds 6 inches to 10 inches in height, and when in free, rich soil it will in one season cover a large extent of ground. It is an extremely free bloomer, the individual flowers measuring 4 inches to 5 inches in diameter, white, changing to rose or pink as they become older, and in the evening emitting a most delicious Magnolia-like scent. It increases rapidly by suckers or underground stems; these often travel a long distance and form tufts of large, toothed or jagged leaves. All through June, July, and August this plant is charming in the evening. Cuttings root readily if taken with a piece of the root. Native of the Rocky Mountains of Upper California, Mexico, &c.

O. MISSOURIENSIS.—A trailing or decumbent low-growing perennial from the dry hills

throughout Missouri and on the Canadian River. It is quite different from the above, though resembling it in its acaulescent habit; the flowers are large and of a soft sulphur-yellow; the leaves thick and leathery, narrow, and of a light shining green. It is readily increased by division or cuttings, and rarely ripens seed in this country—at any rate, it never has done so with us. It thrives best in a rich sandy soil, and if growing on the border will be all the better of a few stones buried round the neck of the plant. Its flowers, produced from June to August, although best in the evening, are often open in the daytime. *O. macrocarpa* is a synonym. There is also a broad-leaved form known as *O. m. var. latifolia*.

O. OVATA, a charming species, is new to cultivation, the seeds having been introduced last year by Mr. Thompson of Ipswich. *O. ovata* is found in moist plains in the immediate vicinity of Monterey, California, and is said to flower in March. The flowers are described as each over an inch in diameter, of a rich bright-yellow. The leaves are ovate or oblong, and exactly resemble those of *Viola primulaefolia*. It is an acaulescent species, and will doubtless be a very useful plant.

O. SPERIOSA.—A charming species, producing an abundance of large white blossoms from April until September. It is an excellent rock garden plant, where on dry sunny places it makes quite a feature. The flowers, at first white, change with age to a delicate rose. The stems are erect, growing from 1 foot to 2 feet in height. It is a native of Red River, Arkansas, Texas, &c.

O. TANACETIFOLIA.—A comparatively rare Californian species, belonging to the acaulescent section and perhaps most nearly allied to the Chilian *O. taraxacifolia*, which it resembles very much in habit and leafage, with the exception of the toothing being carried out to the point instead of only two-thirds, as in *O. taraxacifolia*. It rarely exceeds 4 inches in height and does not like *O. marginata*. The flowers are golden yellow and borne profusely throughout early summer on short stems from the rosette of leaves. It is a neat species, well adapted for the rock garden.

O. TARAXACIFOLIA is well named, as it is readily recognised by its Dandelion-like leaves. Like the last, it belongs to the acaulescent section and makes a very effective rock plant when given a rich, free soil and where its trailing stems can overhang a ledge. The flowers are large, varying from 2 inches to 4 inches in diameter, white when first open, but becoming pink with age. It is a native of Chili, and may be readily increased by division or by cuttings. *O. acaulis* is only a variety of the above with smaller flowers.

O. TRILoba is usually said to be an annual, but with us under cultivation for many years it has not only proved perennial, but perfectly hardy and one of the most free flowering of the genus. It has a dense, caespitose habit of growth, the stems short, the rosette of leaves lying on the soil in most cases. The flowers are larger than in *O. fruticosa*, yellow, very fragrant and produced from early April until the frosts come. The flowers expand mostly in the evening, but they are often open and the plant quite attractive at midday. It is a native of Arkansas, and is readily increased by seed, which it ripens freely.

D.

4579.—Daffodils for a small border.—I gave some little time back a list of the twelve best Daffodils for borders, as I anticipated many enquiries upon this point. I write, however, briefly to name a few good kinds that should be in every border. One is *Horsfieldi*, and another *Empress*. You can select either, but not both, unless you so desire. They are very much like each other, but do not bloom quite at the same time, so you may get a succession. They are "Trumpet" Daffodils and self-yellow in colour. *Princeps* is a good kind, self yellow, as also is *Sir Watkin*, whilst other fine kinds are *Emperor*, a splendid Trumpet Daffodil, the double-flowered *Butter and Eggs*, the late-blooming *Poot's Narcissus*, and many of the less striking, but very beautiful kinds, as *Stella*, *Barr*, conspicuous, *Leedsii*, and the Hoop-tipped *Narcissus* (*N. bulbodidum*), which will succeed out-of-door, although usually grown in pots. Put the Daffodil bulbs in the ground at

once, and ordinary garden-soil will suffice, and the quicker they are planted the better. If you do not mind the expense, plant good clumps, as they are more effective in the spring, a fine mass of colour being obtained. The Trumpet varieties in particular are exceedingly rich thus grown. The list is small, but I have recently given ample information upon the best Daffodils and their culture.—C. T.

4674.—Restoring a lawn.—I should say the brown spots will recover, as seldom indeed are the roots killed from the effects of dry weather alone. However, if they do not become green as readily as might, and the other parts of the lawn look patchy and the Grass weak, it would be a good plan to well scratch the surface over with a sharp-toothed iron rake. This will free the Grass from Moss should there be any in it. The lawn then should be covered with finely sifted decayed vegetable refuse, road-grit, and wood-ashes, adding a handful of soot to every peck of the compost. If the covering is a quarter of an inch thick when first put on no harm will be done, as by raking over the lawn after the soil has been on it a fortnight, much of it will work down amongst the roots of the Grass, and by repeating the raking several times during the autumn, choosing a dry day for the work, the whole of the dressing will disappear. Early in April the lawn should be well swept to remove any small stones that were amongst the soil, afterwards rake it over, leaving a rough surface. Sow law Grass seeds at the rate of 25 lb. to the acre, again rake the surface to cover the seed, afterwards roll the lawn well, repeating this several times after the seed has germinated to make the ground firm. As the new Grass grows freely it should be mown frequently to incite the Grass to spread thickly at the base.—S. P.

— You might prepare the soil in the bare places again and sow seed; but the quickest way to get a good sward is to lay down turves, which in some neighbourhoods may be got very cheaply. I should do this work at once, so as to get the lawn in thoroughly good condition for next season.—C. T.

New Single Dahlias.—The Single Dahlias are less popular than a few years ago, and this is the result of the increasing favour shown to the Cactus class. But still one wants the singles, and a few novelties of great beauty have been shown this year, particularly by Mr. T. W. Girdlestone, who raised the dwarf Tom Thumb kinds, which are useful for edging beds. One of the best new Single Dahlias is Demon, which is a splendid colour, deep-meroon, almost black, and the petals are quite velvety. Phyllis is very showy, lilac, striped with crimson, but the striped kinds are not great favourites. M. G. C. is another striped flower, bold, and very distinct, yellow, striped with orange-red. We hope that the single flowers will not be pushed into the background, as they are showy in the garden, and very charming to cut for the house.—V. C.

4707.—Plants for a rockery.—Notbing but strong-rooting plants can bear the drip of trees. Periwinkles and St. John's Wort is perhaps the best. I find strong clumps of Aubrietias do fairly well, but you must not expect small plants to establish themselves. The American Blue Grass also bears both drought and drip; probably *Thalictrum* would thrive. As a rule, low growing plants of a woody character are the most likely to succeed with you, such as *Antennaria microphylla* and *Erigeron radiatus variegatus*, and the green form of this.—J. C. CLARKE.

— We fear little will grow in such a position. You might try some of the Saxifrages, but these cannot stand drip, neither can such easily-grown things as the Creeping Jenny. My advice is to clear away the rockery, which is a nuisance in your case. It should be the home of many pretty alpines, which cannot grow under trees. After Ferns of the hardier kind, nothing will thrive properly. Ferns, moreover, do not like drip.—C. T.

— The different varieties of Periwinkles, of which there are five or six, are perhaps the most useful of all plants for such positions, growing freely anywhere, and soon covering a large space with a perfect carpet of foliage and flowers. Hardy Ferns also will thrive in the crevices of the stones, and Snowdrops, the commoner kinds of Daffodils and Narcissi, Primroses, Lilies of the Valley, Spleenwort, *Adiantum*, *Compositae* will also all do more or less well.—B. C. P.

ROSES.

SEASONABLE NOTES.

SOME few weeks back I promised to give a few notes upon pot-Roses. The present is one of the most seasonable times, as not only does the routine of work commence now, but it is also the most favourable time to start their cultivation, whether it be with plants lifted from the open ground, or those obtained from the nursery and already in seal pots. A large number of Roses are grown annually by the trade in what are styled 6-inch pots. These do not come much more expensive than those from the open ground, and a great advantage is found in the fact that the whole of their wood is sound and useable to a much greater extent than in the case of larger plants lifted from the open border. Another great point in their favour is their being well adapted for immediate forcing, whereas those from the open need a season's growth in pots, if the best results are to be obtained. Roses may also be purchased in smaller pots, and these are remarkably cheap, considering how soon they return a fairly good crop of bloom. Grafted plants in 48's are the same age as those in 24's, the only difference being that the latter are the best of the batch potted on once more. When purchasing these smaller plants, it is necessary to avoid including any of the climbing varieties. These would not flower during the coming season, as they need to make rods of greater strength than could be the case in such small pots. Varieties like the following twelve are excellent for pot work: *Aca Ollivier*, *Niphotos*, *Augustine Guinoissean*, *The Bride*, *Seppo*, *Rubees*, *Perle des Jardins*, *Madame Haste*, *Madame Faloot*, *Lucinde*, *Gustave Regis*, *Edith Gifford*, *Gombault*, and *Dr. Grill*.

COMPOST AND POTTING.—Let this be a mixture of good loam, leaf soil, and decayed vegetable refuse in about equal proportions. This is a good compost, but the following is also useful, and where difficult to procure one the other may be obtainable: Good garden soil two-thirds, and the remaining third made up of thoroughly decayed stable-manure, with a dash of sharp sand. To either of the above composts there is no harm in adding a little bone-meal. Pay considerable attention to drainage, as much depends upon this, and put firmly, more especially when shifting a plant into a larger sized pot. Far too often this is done without due thought. The soil of the old pot is firm, and unless you make the new soil equally so, water percolates through it too freely, and the result is a sudden outside in comparison with the older ball of soil. Do not prune and introduce to heat sooner than a month after potting. The strong growers will need so pruning, as the nurseryman will have done all of this that is necessary in his endeavour to get a healthy and long rod of growth. One of the greatest mistakes with amateurs when growing Roses under glass is the hastiness with which they excite the plants into growth. This means pucey shoots, and often is the chief cause of blind growth.

INSECTS, &c.—Immediately the Rose commences to grow, one's plants are almost certain to be attacked by some insect. If neglected for a short time this becomes serious, and the results are fatal to a satisfactory crop. But if attended to at once, Roses have as few pests as the majority of greenhouse plants. Mild measures taken early are effectual, and do no harm; but if the insects are allowed to thoroughly establish themselves, they do a permanent injury to the plants. Not only this, but the measures necessary to exterminate them are also injurious, and more than the plant can stand. Let syringing and fumigation be done mildly, even if it is necessary to do it more than once. This is far preferable to injuring the young growth, and so taking the gilt of the first and most profitable crop of bloom.

P. U.

4710.—Climbing Roses.—Seeing that the plants make good growth you cannot do anything to increase the size of the flowers. The aspect being north, there is no doubt these hardy Roses were selected on account of the coldness of the situation. If you are dissatisfied with them, you may remove them and put *Gloire de Dijon* and *Madame Plantier* in their place. No doubt you know the old *Glory*; the other is a fragrant white Rose that flowers in clusters. With regard

to enclosure B, not having seen the latter, I can only suggest that you secure the long shoots to the wall and allow them to remain until the end of the summer to see if they will flower, as I am afraid you are a was bit impatient. If I was sure they are snob rubbish as you seem to suppose, I should say root them out and plant snob Roses as *La Marque* (white), *L'Idéal* (yellow), *W. A. Richardson* (orange), *Reine Marie Henriette* (red), *Rève d'Or* (coppery yellow), and *Cheehuet Hybrid* (red). You must syringe the plants with soapy water to wash off the green-fly. *Ecolouis C* may be a shoot of *John Hopper* but it is very usefull for this Rose not to flower. You had better throw the pruning-knife or nipper—whichever you use—over the garden fence for a year, and give less stimulants, and wait for the effect. If this does not help you I shall be pleased to advise you again.—J. C. C.

— You cannot improve your Roses much in size, &c., as from your description I have little doubt they are *Noisettes* of the *Aimée Vibert* and *Miss Glegg* class. These are naturally very small, growing and blooming exactly as you describe. Your plants in enclosures B and C are probably some stock, from the fact of their growing so strongly and not producing a flower under the three distinct treatments you have accorded them. If you will send me a piece or two of growth, of fair size, I will reply direct whether it is so or not.—P. U.

4711.—Various Roses.—You are evidently in much the same difficulty here as in the previous query. It seems to me you have allowed suckers to grow apace, and must either have purchased badly-worked plants, or else the first killed the Rose, and so allowed suckers to prevail. By all means make up a small parcel of wood and send me no direct, when I will settle the matter as far as stock and suckers are concerned. I shall have much pleasure in replying, as I take a great interest in amateurs' difficulties with the queen of flowers.—P. U.

— I had not read this enquiry when I replied to the one above. Now I have done so I am more convinced than I was before that you either prune your Roses too much by cutting away the flowering wood or you use too much stimulants. The latter is most likely the case, as the information you send leaves no doubt on my mind but what yours is a strong soil, and do not require so much manure as a poor one. I do not think your plants are placed too deep in the ground, nor is it desirable to cut up the plants in the way you suggest. With regard to Roses from which you can cut and come again, you had better grow dwarf plants, and prepare a good-sized bed or border for them. Plant them at once and let them grow their own way for two years. I should prefer, however, to have separate beds for the strong growers, including such sorts as *Gloire de Dijon*, *Souvenir de la Melmison*, *Homère*, *William A. Richardson*, *Rève d'Or*, and *Mme. Plantier*, and another bed or one end of a border for such hardy Tea Roses as *The Bride*, *Countess of Folkestone*, *Marie Van Houtte*, *Mme. Eugène Verdier*, *Mme. Lombard*, *Safran*, and *Mme. Bernard*. If you do not want Roses of high quality, the old-fashioned *Pink Moss* is very hardy, and so is the sweet-smelling *Cabbage Rose*. Then there are the Chinese Roses, such as *Cramoieille-Supérieure*. This variety is just now making a long, dry bank on a gentleman's place near where I write quite brilliant in colour by its innumerable clusters of light crimson flowers. The common white and pink varieties are invariably in flower from early summer until late in autumn. Little's Pet has small, double white flowers, and is a continuous bloomer.—J. C. C.

4699.—Rose culture.—I suppose that if twelve correspondents were to reply to your query, there would not be two of them give the same twelve varieties of Hybrid Perpetuals and Tea Roses as being the best in their opinion for culture as dwarfs. However, I will name those I should choose. H. P.'s: *Alfred Colomb*, *A. K. Williams*, *Baroness Rothschild*, *Comtesse d'Oxford*, *Duke of Edinburgh*, *Duquy Jamin*, *Eclair*, *Jeannie Dickson*, *Mrs. John Laing*, *Merveille de Lyon*, *Suzanne Marie Kodocauschi*, and *Gabrielle Luizet*. Twelve Teas: *Anna Ollivier*, *Amazone*, *Catharine Mornet*, *The Belle Souvenir d'un Ami*, *Souvenir de S. A. Prince Saneet*, *Perle des Jardins*, *Madame Haste*, *Madame Faloot*, *Ernest Metz*, and *Dr.*

UNION PACIFIC CAMPAIGN

4600.—**Scale on Rose.**—Cut the Rose back as close as you can without injuring the plant in any way and rub off the scales; then dress the shoots with the following mixture: 1 lb. of soft-soap, the extract from $\frac{1}{2}$ lb. of Quassa-chips, dissolved in 10 gallons of water; or $\frac{1}{2}$ pint of paraffin-oil, $\frac{1}{2}$ lb. of soft-soap, thoroughly mixed in a little very warm water, and mixed with 6 gallons of water. Keep well stirred and do not allow the oil to float on the top of the mixture.—G. S. S.

4704.—**Roses for show.**—If you had stated the number of blooms you wished to show at one time I could have given you more definite advice. Supposing you wish to show twelve blooms of distinct varieties you ought to grow at least twenty-four, so as to have a choice, and of these you should have two or three plants of each, or you will not be sure of getting the desired number of flowers on a given date. The following will do you good service as exhibition varieties: A. K. Williams, Marguerite de St. Amand, Marie Beaumann, Mrs. J. Laing, Earl Dofferin, Duke of Edinburgh, Françoise Michélon, Dupuy Jamin, Gustave Pignone, Hypolyte Jamin, Madame Sophie Fropot, Mme. Marie Rady, Miss Jeanne Dickson, Mr. James Brownlow, Prince Camille de Rohan, Ulrich Brunner, Victor Hugo, Merveille de Lyons, Capitain Christy, Mme. Nachury, Senateur Vaiese, Madame Prosper Saugier, Jean Soupart, Jules Finger, and Duchesse of Edinburgh. Grow them as bushes.—J. C. C.

—“Hybrid” will find the bush plants far preferable to standards. They will produce double the number of blooms, be cheaper, take up rather less ground, and be considerably longer lived, so that he will easily see there is a great advantage in them over standard forms. Here are a dozen good exhibition varieties, and I would advise three or six of each being grown in preference to increasing the number of kinds. Alfred Colomb, Camille Bernardin, Charles Lefevre, Comtesse d'Oxford, Dupuy Jamin, Mrs. John Laing, Gustave Pignone, Louis Van Houtte, Marie Beaumann, Suzanne M. Radocanashi, Victor Hugo, and Prince Arthur.—P. U.

FRUIT.

WATER MELONS.

IN reply to “R. B.,” “D. S.,” and others, we may say that were our climate sufficiently genial to admit of the culture of Melons in the open air, we should probably place a higher value on the Water Melon than we now do. In countries where the summer heat is intense this fruit is much esteemed, being considered wholesome as well as refreshing. In common with the Cantaloupe, it is a favourite summer fruit with the working classes in large towns in France, and at the large fairs annually held there during the late summer months the immense quantities of them are sold at very cheap rates. Being strong in growth, the Water Melon requires much space for development, a single plant covering, where conditions are favourable, many square feet of soil. One often sees it in gardens in South Germany rambling freely, just as Pumpkins and Vegetable Marrows do with us. In five years in the warmest parts of this country the Water Melon might succeed fairly well, and, considering its hardiness and vigour compared with our most esteemed kinds, we should perhaps do well to give it a place under glass, as it does not need much care, bears heavily, and, so far as I am aware, is not liable to canker. In any case, early planting in rich, free soil and copious waterings are indispensable. The German gardeners plant it out on a gentle bottom-heat about the beginning of May, sheltering the plants under cloches, and gradually inuring them to full exposure, so that by the time frosts are no more to be feared the plants have good hold of the soil, and are ready to respond to the influence of the season. B.

4702.—**Insects on Vines.**—The white woolly spots on the Vines are doubtless mealy-bug, and their presence means a good deal of trouble for the next six months or longer. There is no insect more difficult than this to stamp out, and there must be no half-way business about it, as one pair of insects will be enough to infest a long range of glass-houses if

the temperature be right. The first thing to do is as soon as the leaves are down prune the Vines, and gather up every leaf and cutting and burn them. Then wash the Vines twice over with a strong solution of Gishurst Compound, 6 oz. to the gallon, used warm, the mixture to be brushed in with a spoke-brush or one of those long, narrow affairs which can be deftly handled, so as to find out every crevice. When the Vines are thoroughly clean, wash all the paint inside the house. If possible a coat of paint should be given, and all wall surfaces washed over with strong lime-wash. When this has been done in a thorough manner, remove 3 inches of the top soil from the borders inside the house, replacing with fresh turfy loam, in which a little bone-meal or Petent Silicate Manure has been mixed. Even this will not clear out every insect. A close watch should be kept on the Vines every bright sunny morning through the early spring, and all insects seen moving about killed. The daily look round on fine days to spring is most important.—E. ff.

4651.—**Fruit in a cellar.**—A really dry cellar, from which light is excluded, is the best possible place for keeping fruit. Probably the fruit decays because it was not picked with sufficient care; a padded flat basket should be used, and one layer only allowed to be placed in it. The slightest bruise will cause the fruit to rot before ripening. Another common cause of Pears shrivelling is that they were not picked at the right time. It is not always understood that there are only two or three days for each fruit during which they should be gathered, to keep well for the winter. This time may be found out by going round the trees daily, and

Water Melon.

raising a Pear here and there in the hall of the hand, with a quick movement into the horizontal position. This must be done without the slightest pull on the fruit. And if this trial does not detach it, the fruit is not ready to leave the tree. If left long enough to fall on the ground, it is useless, except for stewing. Constant supervision by the owner is therefore necessary during the autumn months to secure good dessert fruit in winter.—I. L. R.

4698.—**Cherry-trees dropping their flowers.**—Cherry-trees drop blossoms or young fruit sometimes through a deficiency of lime in the soil; sometimes drought may cause them to drop, and if the trees have been growing strongly, unripe wood may have had something to do with it. In the latter case lime rubble worked into the soil would have an influence for good. I think it is unwise to manure the ground overmuch for Cherries, but a mulch when the trees are heavily laden will be beneficial, and I have seen much good follow watering in dry weather, both in spring and summer.—E. H.

4705.—**Fear-tree with cracked fruit.**—Any Pear-tree which has cracked fruit in a season like the past has been in hardly worth growing in that particular position. The principal cause of Pears cracking is deep rooting in a cold, damp soil; but I have known Pears—Glou. Moreau, for instance—where the fruits cracked badly on the espalier and on pyramids, yet did well on east and west walls. It was the warmth of the tree wanted. Lifting the roots out of the soil would be the best remedy.—E. H. Pears often crack in a wet season, but that has not been the case this year. Again, some sorts of Pears crack in some soils more

than others. It is to the latter I think you must look for the cause in your case. The best thing you can do is to regraft it in the spring with another sort. Louise Bonne of Jersey is not subject to cracking, and the sort makes a good pyramid or standard. If you make up your mind to regraft the tree, head down the branches early in February, and put on the colons in April.—J. C. C.

“AMERICAN BLIGHT” ON APPLE-TREES.

If timely precautions are taken to arrest the progress of this troublesome pest when it first appears, time will be saved in the end and the trees greatly benefited. I have no new practice to bring forward as to its destruction, but would draw attention to early removal of the pest. This is of great importance, as many young trees are ruined if left too long. “American blight” is certainly one of the worst enemies of the Apple-tree, and when once introduced into a garden it is only by persistent and repeated efforts that it is kept in check. This pest does not keep on the upper surface of the bark, but gets into the cracks and crevices of the tree, and though the injury caused is not seen at the moment, in time it produces canker, and the trees are ruined. The danger lies in young trees being attacked, as they are so soon injured and disfigured. When very old trees are attacked it is almost useless to try and save them, as the old wounds harbour the blight and prevent remedies being applied. If possible, old trees so affected should receive a winter dressing of clay and soluble petroleum, well mixed together to the thickness of paint. This will do much good, care being taken to thoroughly paint over two or three times the old wounds or cankered parts of the tree, removing all decayed portions before applying the paint. I do not think there is any better remedy for young trees than paraffin or petroleum, using a brush and touching all affected parts. I have also used soluble paraffin and clay at this season with equal success. When young trees are badly infested with the aphid the use of a quantity of paraffin in a raw etete is not a safe remedy. I would prefer using Gishurst Compound in a strong etete, mixing sufficient Gishurst with a little water and well rubbing all over the bark. Soluble paraffin is also a safer remedy than the raw material if a great quantity is used, and is very effective. The use of the raw material must not be condemned, as on older trees it is very efficacious when carefully used. Soft-soap and Tobacco-water applied in a liquid etete is a good remedy. Whatever insecticide is used it is necessary to thoroughly wet or paint the infested places, well rubbing the mixture in with the brush, and to do the work as early as possible. The aphid having a woolly covering, merely syringing or wetting the bark will not reach it; indeed, without hard rubbing it cannot be dislodged. All trees that are near the insect should be removed and burnt, old nails removed and reburnt or heated, and wire dressed with the raw petroleum. If such precautions are taken when first observed, much time and labour will be saved. B.

4689.—**American Blackberry.**—The plant purchased for Wilson Junior is not true to name; it ought not to produce double flowers; these when very double would not be likely to produce fruit. I bought half-a-dozen plants of this variety when it was sent out, and it has produced single flowers which give fruits, but I have been much disappointed with it, and with others of the American Blackberries. They may be very good and very useful in America, but they do not succeed in England. Our own Bramble is better than any of them.—J. D. E.

4695.—**Grafting.**—The best time to graft Apple and Pear-trees is in spring, just as the sap is rising, about the end of March, and the best method for young stocks is what is termed whip graft, cleft grafting being as good as any for regrafting old trees.—E. H.

Late Strawberries, etc.—It may interest some of your readers to know that a dish of Strawberries, Vicomtesse Hericart de Thury, was gathered here on Thursday, Oct. 6, and also on Sunday, 8th, and the White Field No. 1 is in bloom in the hedges.—EDITH CURRIE, Stocken Hall, Shropshire, Glastonbury.

Planting in the open ground.—The best time to plant Potatoes is in early to April. If planted now, and there is a late winter, the plants might die.—E. H.

RULES FOR CORRESPONDENTS.

Questions, queries and answers are inserted in GARDENING free of charge if correspondents follow the rules here laid down for their guidance. All communications for insertion should be clearly and concisely written on one side of the paper only, and addressed to the Editor of GARDENING, 37 Southampton Street, Covent-garden, London. Letters on business should be sent to the Publisher. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Unanswered queries should be repeated. Correspondents should bear in mind that, as GARDENING has to be sent to press some time in advance of date, they cannot always be replied to in the issue immediately following the receipt of their communication.

Answers (which, with the exception of such as cannot well be classified, will be found in their different departments) should always give the number and title placed against the query replied to, and our readers will greatly oblige us by adopting, as far as their knowledge and observations permit, the correspondents who seek assistance. Conditions, soils, and means vary so infinitely that several answers to the same question may often be very useful, and those who reply would do well to mention the localities in which their experience is gained. Correspondents who refer to articles inserted in GARDENING should mention the number in which they appear.

4723.—Romneya Coulteri.—When is the best time to plant Romneya Coulteri?—V. M.

4724.—Best Fuchsias.—Will someone give me the names of the two best Fuchsias for show, one light and one dark?—L.

4725.—Bracken on pasture-land.—Will anybody kindly tell me how to get rid of Bracken from pasture-land?—FRANKLIN.

4726.—Ornamental-leaved plants.—Will someone give me the names of the three best ornamental-leaved plants for exhibition?—L. L.

4727.—Gazania.—Can Gazania be left outside in the late of light where they would do well to winter, or must they be lifted?—H. M.

4728.—Compost for Vines.—Will someone kindly tell me what is the best compost to plant Vines in? Also how many parts of each?—ANKWARD.

4729.—"The Bride" Gladioli.—Will someone kindly tell me the time to put these, and what soil to use, and how to treat them?—BALDOCK.

4730.—Greenhouse plants.—Will someone kindly give me the names of the two best greenhouse plants in bloom for exhibition during August?—H.

4731.—Light-coloured Roses, &c.—The names of the 12 most fragrant light-coloured H. P. Roses and 12 most fragrant Teas would oblige?—MIGNON.

4732.—Ornamental Grasses.—Would someone give me the names of several good ornamental Grasses, and say when they should be sown?—G. I. H. D.

4733.—Tree Carnations.—Intend growing some Tree Carnations, and should be glad if anyone would tell me the names of a few of the best sort?—A. R. S.

4734.—Messembryanthemum and Double Petunia cuttings.—Will these, struck in boxes, kept in a cold frame, or must they be kept in greenhouse?—H. H.

4735.—Cornflowers.—Should Blue Cornflowers be sown now in the late of light out-of-doors or in early spring for flowering in a bed with Roses at the same time?—H. M.

4736.—Striking evergreens.—If I put slips of evergreen bushes in the open ground, will they strike root and grow, and the proper time for doing so?—M. ANGELO.

4737.—Scale on Peach trees.—I have some Peach-trees badly infested with scale. How can I best get rid of them? Any information will be thankfully received.—FRANCHISE.

4738.—Cape Gooseberry.—I shall be much obliged by information as to treatment throughout the year in pots (hot, moist, pruning, winter temperature, ventilation, &c.)?—J. D. M.

4739.—Lining a garden.—Will someone kindly tell me how much quicklime would be required to give an acre of garden a good dressing; also how should it be applied?—WEST RIDING.

4740.—Manure from Pine-needles.—Will anyone kindly tell me if I can make manure out of Pine-needles, and how? Or if I must burn them will the ashes be good for manure?—FRANKLIN.

4741.—Perial Ranunculi.—Will you kindly inform me if Perial Ranunculi would grow and bloom well in a box in a cool greenhouse; and would they do so earlier than in the open ground?—F. G. S.

4742.—Destroying weeds.—I want to put a liquid on my paths to destroy weeds, but am afraid to buy the weed-killer because of the poison, as I keep poultry. Will someone please tell me of a simple and safe one?—M. ANGELO.

4743.—Mignonette, &c.—Would someone tell me if Mignonette and Salpiglossis seed were sown now under glass they would flower through the winter? And how can I get the Mignonette high? Any information will oblige.—G. J. D. D.

4744.—Pteris hastata.—Will anyone kindly tell me how to grow the above, also the kind of treatment it requires? I have tried to grow it in the greenhouse with other Ferns, but as soon as the fronds come up they die off brown.—H. ROBINSON.

4745.—Removing Asparagus.—I have a bed of Asparagus that I particularly wish to remove to another site this month. Will someone kindly inform me if this may be done with safety? The plants were two years old when planted in.—J. O. FUSSELL.

4746.—A White Chrysanthemum.—Will anyone kindly say if there is a white Vivand Morel Chrysanthemum? I have one of my Vivands having two flowers, each over 12 inches across, pure-white, and I think an improvement on the true variety.—J. ROBINSON.

4747.—Thorn hedge.—In the centre of my garden there is a row of Thorn-trees about 6 feet high, running north and south. Would it be best to dig them up, or is the amount of timber they afford of greater value than the nutriment they extract from the soil?—L. L.

4748.—Strawberries not bearing.—Referring to article in GARDENING on Strawberries, page 424, September 30, can you tell me of any way to find out when the Strawberry-plants are mellow? I have had some Hants-bells not doing well and bearing badly.—CHARTER.

4749.—Treatment of Gloxinias.—Will someone kindly give me a little advice on Gloxinias? I have some plants that have been rather neglected. If you will kindly give me a little advice on potting and soil I shall be glad. They have been standing in the same pots for two years.—WILLIAM GRAY.

4750.—Tomato growing for market.—I should be much obliged to anyone kindly informing me the title, price, and name of publishers of a small book on Tomatoes growing under glass for profit, as I am thinking of growing Tomatoes for the market when I go to England next spring?—TOMATO GROWER.

4751.—Goronilla and Cytisus.—I have some of these in fairly large pots which I sown last year, and have been outside since May. The pots seem quite filled with roots. Could I stake the old soil from them and plant in the same pots with fresh mould, and, if so, what sort should it be?—BALDOCK.

4752.—Blight on Apple-trees.—I have several large and productive Apple-trees encrusted on both trunk and small branches with a white blight, sometimes all round the branches, sometimes hanging in crystals. I have washed them with soap and sulphur without much effect. Is there a remedy?—POMONA.

4753.—Planting a Pear-tree.—I should be glad to know if a Pear-tree should be planted now or in spring? I wish to plant a Williams' Bon Chretien Pear, and train it umbrella-fashion. Any details for soil and cultivation will be gratefully received. The position is sunny and sheltered, and is the late of light.—H. M.

4754.—Young Vines.—Last spring I planted several young Vines, and they are each about 20 feet of growth, and this is ripening nicely. The rods are each about 1 1/2 inches circumference at the lowest wire in the vine. How much growth ought I to leave above the lowest wire at the next winter pruning?—J. W.

4755.—Scale on Ferns.—I have scale on nearly all my Ferns. I should be glad to see some advice how to destroy it. I have a lot of young Begonias just up from seed I saved this year. What treatment shall I give them during the winter? Shall I dry them off or keep them growing after they are potted off singly?—H. W. C.

4756.—Growing Roses.—I intend going in this year for Roses. Aspidiotus kills the young of the 12 best dark hybrid roses, and the name of the best white and lighter-coloured ones.—INQUIRER, Cork, Ireland.

4757.—Cooking Custard Marrows.—Will someone kindly tell me how to cook Custard Marrows. Some were boiled more than 10 hours and remained so hard as bricks. They were with great difficulty cut open, and the inside was found to be cold and rattle, but the outside had to be thrown away. Is that their usual state?—L. J. L.

4758.—Treatment of a Banana.—I had presented me a nice plant of a fruiting Banana nine months ago, which has reached to the height of 4 feet, growing in a 12-inch pot. Would some grower of the above kindly tell me what size pot I should put it in to fruit, and then should I expect it to show fruit? Any cultural notes would oblige.—INQUIRER.

4759.—Sweet-scented Carnations.—Will someone kindly tell me which of the following Carnations are most sweet-scented?—Duchess of Fife, Countess of Paris, Geometrica, Her Majesty, Keston Rose, Mrs. Frank Wray, Mrs. Reynolds Hole, Nurse Still, Pride of Great Britain. I shall be glad to know the names of other scented ones with large flowers.—DIAMANT.

4760.—A draughty corner.—I have a very small plot of ground, 9 feet by 4 feet, contains a good soil, faces the north, and in a draughty corner lot, gets no sun. Now what could I put down there, please? I would any kind of fruit-trees or vegetables, or, failing these, could anything evergreen be put in? The district, near Manchester, is also rather cold too.—QUEEN'S ROAD.

4761.—Flower-farm in the Riviera.—Which part of the Italian Riviera between Ventimiglia and Leghorn is most suited for a flower-farm? Does it require a large sum of money to begin with, and about how much? Which would be the best market for the sale of the produce? Could a practical man undertake the heavy work be obtained by advertising in GARDENING?—Q. M.

4762.—Lawn-tennis ground.—Advice wanted as to best winter treatment? The situation is somewhat low and damp. The Grass wants strengthening and enriching, and anything that assists drainage would be beneficial. The soil underneath is poor and sandy, and for some years the Grass was neglected. Our road-sweepers, I fear, contain no granite, and would not be of much use.—AMMOBY.

4763.—Grapes not colouring.—I have a large vineyard planted with Gros Colman grapes, which, although a good size, are not colouring very fast. I should be much obliged if anyone who has had experience would tell me if it would be best to keep the house open top and bottom a little at night to hasten the colouring, or whether they are best shut up tight at night? I am heating nightly with hot water.—ANXIOUS.

4764.—A sloping border.—I am forming a sloping border facing west in order to hide a path which is a right way of way. At the back of the border, and overhanging it are some Elms and Oaks. What should I plant in the border to make a screen that would be most like to grow under the trees? Would Potentilla Rubra be likely to answer in winter? The climate is cold, but the situation is open.—E. ST. ANTON.

4765.—A Laurel shrubbery.—I had a Laurel shrubbery planted 20 years ago, but now overhanging by Oak and Yew-trees, and shaded on the east side by the garden wall. The Laurels were kept cut to hedge height. They are now dying off at the top, and require cutting down, leaving only a few green sprouts from the roots and the bare soil. What can I do to this, and what shrubs could I put up under these trees?—MONA.

4766.—Building a small greenhouse.—I should be obliged if someone would give me advice as to building a small span greenhouse, about 12 feet by 10 feet? I am anxious to build it myself, and I am a good enough joiner to do such work. What I want is the measurements, kind of wood, &c. Is there any magazine which has published any drawings of such a house as I want? I should be thankful for any tips on the subject.—WRS.

4767.—Dwarf blue-flowering plants.—Will someone kindly suggest a dwarf blue-flowering plant to serve for outside bordering? I have two long beds, 4 feet wide, with Carnations down the centre, and purpose having, when the time arrives, Scarlet Geraniums on each side, and to complete the beds require an outside edging of blue. I do not care for Lobelia, but should prefer some other plant growing from 8 inches to 6 inches in height.—T. W. C.

4768.—Craspers on West-end houses.—I should like to see a great favour if someone would be so good as to state in next week's number the names of that will creep outside on many houses in Grosvenor street, Grosvenor place, and, in fact, hanging from most houses in the West-end? The root is not in pots, but generally on the outside area, growing up the walls and hanging therefrom. It looks like a kind of Virginian Creeper, but that is not what I am told.—BOLESLAW.

4769.—Tropaeolum speciosum, &c.—Would someone kindly give me information as to the name of the following plants: Tropaeolum speciosum (Flame Nasturtium), Spiraea alba, Myrtle odorata, Hesperaloe parviflora, Trollius dahuricus (Globe-flower), Galium (Callifloria), Dahlia, Funkia grandiflora, Romneya and Perennial Sunflowers, which are raised from seed and which from plants, and when they should be planted? Any information will be very welcome.—G. I. H. D.

4770.—Asparagus and wireworm.—I have a field of about four acres planted with Asparagus, and I find the wireworm very destructive between October and March, the time the Asparagus is in a dormant state. Will anyone tell me if soil, sown now, would destroy the wireworm and not injure the Asparagus? I propose sowing salt or nitrate of soda next March, which will benefit the Asparagus and destroy wireworm, but in the meantime should like to know what will destroy the wireworm and not injure the Asparagus?—W. E. H.

4771.—Grapes for a cold-house.—I observe in GARDENING, 4623, in answer to an enquiry respecting best Grapes for cold-houses, a correspondent names Black All-Groves as being not at all the best. As I have understood from several amateurs that this Grape frequently refuses to do much under cold treatment, I shall be glad to have another opinion. Perhaps some amateur will give his experience during the season? In Trentham Park considered a good variety for a cold house. Does it set and ripen as easily as Black Hamburg?—TREVOR.

4772.—Treatment of Ferns.—Will someone who understands Ferns please to tell me why Ferns go speckled with white spots, and why the Holly Ferns and some of the Ferns are covered with woolly bugs? They are in a greenhouse in which there is a Vine, and never get an over-dewy watering, because the gardener says the moisture thus caused would spoil the Vine. I have had a mite-bug hung between them and the Vine during the hottest parts of the summer. I should like to know if spraying the Ferns would injure the Vine, the Grapes of which are always shrivelled to some extent?—ASTORIK.

4773.—Apples, &c. for a small garden.—Would someone tell me if the following would be good varieties for two rows of bushes in a small walled garden? Apples—two of Cox's Orange Pippin, two of Ecklinville, and one each of (which does well in a wall in this country) Sturton's Lane's Prince Albert and Worcester Pearmain. Cherries—May Duke and White Heart. Plums—Early Prolific and Drap d'Or, and two Victorias; also, for north wall, Belle d'Or and Cherry, and for south wall Green Gage and Golden Drop Plum. Soil, peaty on gravel; county, Cornwall. I have Morello Cherries and several varieties of Apples, but no Plums.—A. H. M.

4774.—Freaks of Nature.—"One of the most wonderful freaks of Nature ever known in this country may be seen at Biston, in Lincolnshire, where a tree which has been for many years producing Apples this season. The tree bears resemblance to both kinds of fruit."—Christian Herald, September 21st, 1883. Can this be possible? I have some Plum-trees that do not bear any fruit at all. I should not mind if they did bear Apples, or even Pears, so long as they produced something. I have also some Pear and Apple on the pyramid and bush that bears nothing. I should be glad if anyone could tell me how to make them bear? They are annually pruned—that is, the young growth cut off. Would it be better to cut off the lower branches, thin out upper branches, and let the tops lower go up so as to get more sun and county taken from a tree that did not appear to have had a kulle put into it for 20 years, and numbers more close to it that were the same, but had more fruit on them.—H. B. Hants-road, Finsbury-park, London, N.

4775.—Cabbages clubbing.—Can you tell me why I am so unfortunate with my Cabbages, Brussels Sprouts, &c., clubbing? I have been an amateur gardener now for about ten years, and have been very successful with all my vegetables until during the last three years have been troubled with this disease. I have a good piece of ground, and manured it well for four years. I have only put a little during the last three or four years. I buy my seed from one of the best seedsmen in London, and the plants thrive until they are transplanted, when about three-fourths of them are affected by clubbing, and are consequently quite useless. Thinking this was caused possibly by wireworms, some of which I have some across in turning my ground over, I covered the garden with gas-lime, but

BOULTON & PAUL, MANUFACTURERS, NORWICH.

**PORTABLE WOOD & IRON BUILDINGS
FOR LEASEHOLD PROPERTY.**

Cool in summer; warm in winter; can be inhabited the moment they are finished; no possibility of damp.

Shooting and Fishing Boxes, Gentlemen's Residences, Stables, Coach Houses, &c., Game Larders, Gardeners' & Labourers' Cottages.

Descriptive Catalogue of all our Manufactures, including Iron Buildings for Shooting and Fishing Lodges, Stables, Huts, Kennels, Poultry Appliances, Greenhouses, Garden Frames, &c., free on application.

Laundries, sunsets, and additional accommodation to existing dwelling-houses carried out.

Testimonial from Herbert Greg, Esq., Sept. 13, 1893: "I am pleased to say the work was done very well, and have no doubt it will be very comfortable when finished."

BOULTON & PAUL, NORWICH.

JONES & ATTWOOD, IRONFOUNDERS, STOURBRIDGE.

Supplied with various arrangements of Pipes. For Greenhouse, &c. Catalogue free. Jones' Treatise, "Heating by Hot-water," 120 Pages, 50 engravings. Cloth, 2s.

STOVES

TERRA-COTTA—PORTABLE—FOR COAL. GREENHOUSES heated 24 HOURS for about ONE PENNY without attention. ROBERTS' IMPROVED PATENT PORTABLE TERRA-COTTA STOVES for COAL give pure and ample heat with common coal, or coal and coke. For GREENHOUSES, BEDROOMS, &c. Pamphlets, drawings and authenticated Testimonials sent. See list at Post-office. T. ROBERTS, 34, Victoria-st., Westminster.

HEATING APPARATUS, From £4 4s. and upwards.

VIOLETS (SINGLE AND DOUBLE).

THIS has been an exceptionally trying year for Violets, and very much more than ordinary care must have been given if they are now in fine, healthy condition, as they are essentially moisture-loving plants, and from the date when the runners were potted until recently it has been unusually dry, and with an amount of direct sunshine unequalled for many years. Under these conditions it is no wonder that we hear of failures on all sides, for when Violets are grown by the acre artificial wintering is a very costly affair, and unless it was done this year there was no chance of success, as the spring was even more intensely trying to the fresh-planted young plants than the heat of summer was to such as survived the ordeal. The single Russian Violets of the Czar type are very largely grown for market, and the usual plan is to make fresh beds every year, digging up the old plants, and replanting the best of the young rooted runners on deeply cultivated and well-enriched soil, and this year those who prepared the beds well have cause to rejoice, for plenty of menure and a deep root-run is better than any kind of artificial watering. Keeping the runners out close off is of the greatest importance, so as to concentrate the strength of the plant in the crown. Such plants will now be ready to burst into bloom, and produce fine flowers on long foot-stalks, and it does not take many blooms to make a bunch. Backed up by its own foliage, the flowers look lovely, and sell freely. Double Violets are seldom satisfactory if left entirely in the open air, but bloom with great freedom if lifted and placed in frames at this time of year. The routine of culture is very similar to that adopted with the single kinds, only that being of a tenderer nature they require more care in all stages of their growth. The most useful varieties are the old Neapolitan and its near ally, Marie Louise, which in many respects is superior to the older variety, and Comte Brezsa (white). During such summers as the pasta partially-shed position for the beds is a great gain, as it reduces the necessity for such continuous waterings; but great care must be taken to keep red-spider from getting a hold on them, for it soon destroys all the foliage. All runners must be cut close off, and by the end of September the plants will be ready for lifting with good balls of earth, and replanting in frames set in the best position for catching every ray of sunshine. Frames that have been in use for Cucumbers during summer answer well for the winter quarters of double Violets; they require plenty of air at all times when there is no frost. I find a good layer of Coconut-fibre spread between the plants of great service, both in keeping the roots from drying, and it also makes a clean surface for the blooms to rest on. I may add that the blooms should not be picked until they are fully grown.

J. Groom, Gosport.

Classes of florists' Tulips.—The differences between the various sections of Tulips are puzzling to amateurs, and in this is the Ameri-

can purchaser bulbs I may point them out. The first stage of a seedling Tulip is always, without exception, a self-coloured form, which is called a breeder—either rose breeder, hybrid breeder, or hizarre breeder, according to the colour of the flowers. The offsets are always subject to break into a flamed or feathered flower. The three sections are easily distinguished, not by the colour of the base, but by the colours of the flowers as follows. **Roses:** All rose-coloured flowers have a white ground when broken, or rose-coloured with a white base in the breeder stage. Hybriders include purple of all shades on a white ground when broken, or purple with white base in breeder stage. Bizarres include all those with yellow grounds, or yellow bases in breeder stage.—V.

NOTES ON THE TREE-PEONY.

THE Tree-Peony is one of the most beautiful of early summer flowers, and this note is prompted for the reason that the planting season is at hand. We owe much to the Japanese and Chinese for the present perfection of the plant, as very few of the varieties that now charm with their colour or form are of European origin. It is somewhat difficult to account for their comparative scarceness. They are grown in pots, but not so often in the open, where, in suitable positions, they form bold, graceful, and beautiful groups, very distinct from the herbaceous varieties in expression. One great difficulty is that when the winters are mild, the plants commence to grow, and then comes a cold wintry spring, to the severe injury of the new leaves. The remedy is to shelter them from keen easterly winds and early sun, but, of course, this protection against the early sun, that promotes too rapid a growth, must cease when all danger from frost is over. In many places, however, in warm situations, it will not be necessary to give even slight protection, and where Tree-Peonies succeed well there are few plants when in full bloom that are more beautiful either in leaf or flower. A single plant on the lawn is delightful, spreading about in its own way, and we get not only the beauty of the flaming flowers, but many colours on the young leaves as they show in spring. Much the same kind of soil that suits the Herbaceous Peonies will also do for the tree varieties; but it must not be too heavy, although plenty of manure is necessary. We have seen very beautiful clumps in almost sand, but a happy medium is best—that is, a mixture of loam and well-decayed manure, made lighter if too heavy, by the addition of sharp sand. Tree-Peonies are usually propagated by grafting on the roots of the herbaceous kinds, and bury the graft in planting a little under the soil, so that the plant may become in time on its own roots. If the specimens are not very large at the commencement, about three years will elapse before they will bloom respectively, but after that period a profusion of flowers may be looked for, the beauty of the shrub increasing with age. If pot plants are put out the best time for this operation is spring, when all danger from frost is over, but the usual months for planting are September or October, the former for prefer-

ence, so that they may become fairly well established before cold weather occurs. There are many varieties, and the finer ones may be reserved for pots. The best are Bijou de Chrusan, the flowers double, very freely produced, but the plant is, unfortunately, not quick in growth. Beauty of Canton (menue-purple), Blanche de Noisette (flush), Colonel Malcolm (purple-magenta), Comtesse de Tador (salmon, double), Impératrice Josephine (rose or violet, very double, bold and handsome), Laoten (white, single), Madame Laffay (rich pink, the colour deeper in the centre of the flower), and Reine Elizabeth (salmon-pink, an excellent variety for indoor culture). V. C.

4703.—Enlarging a garden.—It is too late for this year to sow anything that will do to dig into the ground. Next season you may sow Turnip-seed as the summer crops come off, and in the autumn dig in the crop of green stuff. If the Turnip-seed is sown fairly thick there will not be any large bulbs to the plants. If you are afraid that there are wireworms in the new soil you had better substitute Mustard for Turnip. A friend of mine has certainly proved that when green Mustard is dug into the ground that the wireworms do not increase if it does not destroy them. But the Mustard must be dug in before the frost is severe enough to injure it. If the new ground is covered with green sward you had better have the turf shredded, which would destroy a good many insects.—J. C. C.

—To wait for a green crop to grow for the purpose of digging it in loses valuable time. A good dressing of stable or farm-yard manure and trench it up, leaving the surface open and rough for the weather to set upon it. If the ground is light leave the manuring till next February, but trench it roughly now.—E. H.

4656.—Spring bulbs.—The pots in which spring bulbs, such as Hyacinths, Daffodils, Tulips, &c., are potted should be buried in a bed of fine coal-ashes—i. e., the ashes after they are riddled from an ordinary wire cinder-sifter, in the open air. These ashes are very useful in gardening, as they are the best preventive of worms getting into the pots, and are usually free from insects, while slugs and snails object to travel over the rough surface, and so the plants are safe which stand on a bed of ashes. This should be arranged in the corner of a back-yard or garden in a sheltered, sunny position for early bulbs, which are best covered up with the ashes to the depth of 2 inches or 3 inches until they have made their roots, for their well-being largely depends upon this process taking place before they are excited to leaf-action by the light. In three weeks or a month from the time they are buried they may be taken up, the pots washed, and the upper ashes cleared away, when they will grow well in a greenhouse or a window without much fire-heat.—I. L. R.

4731.—Miscembyanthemum and Double Petunias.—Neither of these can be relied upon in a cold frame. The Petunias will certainly perish with damp, even if the frost is kept out.—E. H.

—Generally speaking, it is necessary to have artificial heat in order to winter plants successfully under ordinary conditions. In a very warm situation in the extreme south or south-west, near the sea, some of the plants might survive an average winter; but, as a rule, heat is requisite, damp, as well as cold, being very troublesome without it.—E. H.

GARDEN WORK.*

Conservatory.

For two or three weeks at any rate other things must be subservient to the Obryonanthema, and this means open ventilators at any favourable opportunity, with just enough fire-heat to keep the atmosphere buoyant and free from damp. What a terrible plague the arriags have been this season! Night and day we have been on their track, and still some harm has been done. Where the right sorts have been grown there will be a grand display through the autumn and winter months, and if snob varieties as Ethel and Mrs. Deane have been grown in quantity there will be plenty of blossoms to outlast Christmas and later. Discontinue the use of fumigants when the flowers are expanding. Mildew will probably be present on a number of the sorts. The Queen race are very subject to this pest, and if not taken in time a good deal of damage will be done. Now that damp weather has set in mildew may appear in some of the soft-wooded Hesthas, and on the young wood of Marechal Niel and other delicate-growing Tea Roses. This should be promptly met with black sulphur. With Roses planted out in the greenhouse the young shoots are the worst attacked, and these may be cut out without injuring the plants as late sheets will not flower. Soarles' Paragonium F. V. Raspall in good-sized plants will be very effective now, and these must be kept in a light warm-house near the glass, or the flowers soon damp. Bonvardias are now very bright and effective in a light position and temperature which works at night from 50 degs. to 55 degs. This is a very good temperature for flowering stuff generally. It will be better to discard the syringe till the days get to lengthen again, and damp is so fatal to flowers. If insects appear on any plants of moderate size, such as Cinerarias, Paragoniums, &c., it will be more economical to dip them in a liquid insecticide than to fumigate with Tobacco. We are using Sunlight Soap, dissolved in warm water at the rate of 4 ounces of soap to the gallon, adding a wineglassful of paraffin-oil to each gallon of water. The disturbance of the mixture in a lifting plants in and out will keep the oil fairly mixed. A tub or an old tin bath do very well for dipping purposes. One dipping is not sufficient, but if followed up the insects will soon be got rid of. The earliest potted bulbs will now be coming into flower in the forcing-houses. Roman and Italian Hyacinths are very sweet and useful for cutting.

Stove.

There will be no scarcity of blossoms here now. Among the easily-grown plants suitable for a small or moderate-sized house are Flumbago Rose (small lanternum). It has lavender-like spikes, resembling an enlarged Ageratum with a lignous habit. The plant forms a neat little specimen, and the flowers are lasting; may be moved to the conservatory when in bloom. There are also the Bilbergias, Aphelandras, Franciscoas, Bogotias, and Juncos, the cultivation of which presents no difficulty. Now that brick fires have to be kept going regularly, losses will have to be reckoned with, and it must not be forgotten that prudence in dealing with the stove has both about and expense. Among the winter-flowering Begonias which are now found so useful will be included the following: Isidria, mantata, nitida alba, sordida, comperifera, gizefata, carminea, and lucidissima. These are best obtained from early spring cuttings, or if large plants are required strike the cuttings in autumn and grow on through the winter, keeping the leaders well pinched. Very large bushes of most of the above may be obtained from autumn-struck plants by the next autumn.

Forcing House.

This department will be found very valuable now. The early-potted bulbs may be brought in to get them on, and Lily of the Valley may be soon started to get them in bloom by Christmas. It is as well to give Vines in pots all the rest possible, and then bury them in a hot bed after the start has begun. The forcing of early Grapes does not receive the same attention now as was given to them before the introduction of Green Columns and other late-keeping sorts, but there is no comparison between early plants like Ambergris and late Columns as regards flavour, although the latter, when well ripened, are not so bad. I like them better than Alicante.

Unheated Greenhouse.

We are approaching the time when frost sufficiently sharp to penetrate the unheated house will soon be here, but if the Tuberosas, Begonias, Fuchsias, and other tender plants which have been grown for their summer beauty have been potted away, either in the cooler or plunged in Coco-nut-fibre in a corner of the house, where paper or some other kind of covers can be used to shelter as required. Good bushy specimens of the Gold and Silver Eucalyptus will be very effective. These are very pretty when trained up walls, and for this purpose may be planted in the border, but when grown in pots they are used to mean decoration with considerable effect. The Obryonanthema are at the present moment the leading feature, but a severe frost will injure them, and therefore when kept in a cold house a cover of some kind will be very desirable, but it should only be used when absolutely necessary, as a damp close atmosphere will be almost as injurious as frost.

Cucumber House.

Sixty-five degs. will be high enough at night, with as much rise as can be had from sun heat during the day; but be careful about the fire, not so much on account of the dryness of the soil as for the injury which strong fires very often do. It is the custom nowadays for large consumers of fuel to make contracts only in advance of the probable requirements. All through this coal strike we have had cheaper fuel than last year, simply because arrangements for the winter's supply were made long before the strike took place.

Cold Frames.

Give all the air possible to frames which contain Cauliflowers, Lettuces, Endives, Violets, and other hardy plants, but keep out cold rains. At the same time the roots

must have sufficient moisture. Frames containing cuttings of Calceolarias, Variegated Eucalyptus, Santolins incoas, and others edging an unprotected plants may still require a little shade on bright days, and the soil must be kept moist. Hyacinths and other bulbs for forcing will require about six weeks in the plunging-bed to make roots.

Window Gardening.

Good judgment is necessary now in watering all indoor plants. Tap each pot before watering, and be guided by the sound. If in doubt after this lift the plant and test its weight. Use only soft water. More plants are killed by over-watering than by forgetfulness at this season. At the same time lullage plants, such as Palms and Ferns, must not be allowed to get too dry for healthy root action. Aralias are more often injured by having too much water than too little.

Outdoor Garden.

In looking round among the hardy flowers the thought arises, why not plant more Aster n Starwerts, and let them grow into huge bushes? The flowers are bright and peaty for filling small vases, where heavy flowers would be out of place. They will grow anywhere, and are especially useful for filling up bare places among the shrubs in a garden. The custom of placing white flowers termed nurseries is well enough in itself, but it adds seriously to the expense of laying out new lawns, and further, it thins out the permanent things are often seriously injured. This is why I do not recommend this nursery system of planting. Plant those things that will look best to the future, and fill in with good hardy subjects or annuals in good-sized masses. I suppose everybody has done planting the early flowering bulb in November is the best time to plant Tulips. The 20th, or Lord Mayor's day, was the favourite time of the mid-fashioned florist, but it is not necessary to draw hard and leafless. Plant when the beds are in good condition, and let it be as near the 9th of November as possible. Loss no time now in getting to the Roses, and those who do their own propagating should plant standard and dwarf Briars, and set out cuttings of Blue and Manetti, and gather seeds from the Wild Briars on the hedges when ripe.

Fruit Garden.

Many are now busy planting fruit-trees, or preparing for that operation. There is more than one way of doing this. Many trees are seriously injured by being planted too deep, especially in heavy soil. If the collar of the tree is buried in a mass of heavy cold soil the tree will not thrive. Better by far make the surface soil the tree really desires a good bloom. The second week in November is the best time to plant Tulips. The 20th, or Lord Mayor's day, was the favourite time of the mid-fashioned florist, but it is not necessary to draw hard and leafless. Plant when the beds are in good condition, and let it be as near the 9th of November as possible. Loss no time now in getting to the Roses, and those who do their own propagating should plant standard and dwarf Briars, and set out cuttings of Blue and Manetti, and gather seeds from the Wild Briars on the hedges when ripe.

Vegetable Garden.

The falling of the leaves from the trees will place in the hands of the morning gardener a very useful course of heat that is loose and reliable for bringing on Beans, Peas, and Asparagus. Asparagus will force now on a hot-bed anywhere that the first bed takes a little more warmth to come into action than will be necessary later on. Young 4-year-old roots which have not been out from make the best stuff for forcing early, and will not require so much heat to start it into work. In forcing Rhubarb, start with an early variety, and leave the Victoria, which is a fine Rhubarb, for later use till Christmas or later. It is a great help to the gardener when he has some means for forcing early vegetables, and makes his intercourses for forcing the kitchen much easier. French Beans may be started in pots as often as it is necessary to meet requirements. French Beans cannot be obtained in winter without plenty of heat, and they must be grown in a light house. It is time all root crops were secured and stored away in some place where frost cannot injure them. All roots retain their flavour and condition better, when in contact, or nearly so, with moderately dry earth. It is well known that Potatoes keep better when covered with soil in rather than in open air. Carrots, Beet, Turnips, &c., but all root stores should be looked for occasionally, and everything in the nature of decay removed. Trench over weedy ground. Do not manure light land till January or February. Cover the manure with soil to absorb its gases.

E. HORDAT.

Work in the Town Garden.

Tomatoes are still doing well, especially where they can have the assistance of a little fire-heat at night, and on dull or wet days. Even in the open the plants have not yet been injured by frost, but the temperature is now too low, and the sun not sufficiently powerful, to enable the fruit to ripen to any extent. Plants that have been grown in pots or boxes of moderate size stood or plunged outside, in stages of development, and it they can be brought into a light and well-heated house the fruits will ripen perfectly. This system has much to recommend it, for plants in pots or boxes can often be accommodated where it would be impossible to plant them out, and on the other hand, where there is nothing but the rich soil of an ordinary garden border available, covering the roots in pots or boxes is also, say 7 in. to 10 in. deep, with well-rotted manure, and prevents undue luxuriance of growth. The

pot are, of course, to be plunged in the soil rather deep than the rims. Tomatoes planted out under glass now require very little water, unless a good deal of artificial heat is employed, and even then much less than during the tropical weather experienced on long days. But in pots, however, need rather liberal supplies, or at least according to the temperature. The plants will seldom fall to swell and ripen satisfactorily with the aid of a sufficient degree of warmth; but after that time considerable difficulty is often experienced in getting the flowers to set, especially during inclement weather or in a smoky atmosphere. Young plants from either seed or cuttings, for early fruiting next season, must be wintered on a high shelf, near the glass, in a light and well-ventilated structure. In a moderately pure atmosphere little trouble will usually be experienced in wintering them, but when there is much smoke or fog about they are very uncertain subjects. Cucumbers, on a rule, do very little good to town gardens during the winter season; in warm summer weather they grow and fruit freely, but for winter work pure air and free light and sun are absolute necessities. Large-flowering Pelargoniums ought to be accommodated in a very light and airy structure now and throughout the winter, with a temperature of not less than 45 degs. to 50 degs. at night. These plants do best on open sites where a current of air constantly passes through them; and they must also be very carefully and sparingly watered, none being given until actually required. The Zonal and Ivy-leaved geraniums will do in a temperature of 5 degs. to 10 degs. less, but even these like enough warmth to keep the air in motion and prevent damping.

THE COMING WEEK'S WORK.

Extracts from a garden diary from October 28th to November 4th.

Commenced to prune Pear-trees in walls. Having a good deal of pruning to do, it is necessary to begin early, and the trees are taken in rotation as the leaves fall, the Pear on walls generally coming first. The Peach and Apple, and Plums, and the Apricot and Nectarine being left till the last. In pruning hardy fruit against walls there is little risk of the plants being injured by the frost; but even the foliage is quite so injurious a disease from the wall as when close to it; and there is the disadvantage, when the spurs are permitted to extend, that the shelter of the wall is to a certain extent lost. Whenever a spur appears to be getting too far from the wall I cut it out, and let a young spur take its place. Four-trees on a wall in a fertile country are as paying a crop as can be grown. To have the trees well lit, in a fertile condition it is necessary to keep both roots and branches well under control. Pruned Peaches in early houses. I have not been troubled with scale for years, and never paint the trees with anything. For many years past I have used Gishurst Compound, strong enough to kill the eggs of insects and the spores of mildew should any be present, and beyond that paint and washes are not required. The house will be closed for forcing about the end of December; the branches of the trees will probably be left loose till bearing the time has started, although if a spell of bad weather sets in the wood may be tied in earlier. I try as far as possible to get on with the outside work so long as the weather keeps open, and carry on the inside work when bad weather comes. The forcing Strawberries have all been plunged, but not all in coal-ashes, as there was not enough; and fled when the pots are packed in dry leaves, and covered with a layer of straw, the roots do not suffer. The drying power of a long frost has an injurious effect upon the plants. In fact, plants in pots, unless plunged, are in a worse position than are those growing in the open ground. All Strawberries intended for forcing will be kept as much as possible in the open air, merely sheltering from heavy rains. Just received a bundle of Tea and other Roses, and as the beds were ready they were planted in arks. It is a mistake, I think, to send hundreds of miles away for Roses, as there are good Rose nurseries in many districts, and it is always best to buy Roses where they can be seen growing. Cheap Roses and cheap fruit-trees very often disappoint. Above all things, if really good plants are required, order early. Immediately after planting state the standards. Some among us may object to standards; we may say they are short-lived, they are expensive, and at the best they are sawn up and discarded, and looking to these we will give up standards. All this may be true, but there is a place in every garden for a few standard Roses. Potted up a number of roots of Mint and Tarragon to come on steadily under glass. Made up a couple of Mushroom-beds in house. I make it a rule to keep all root-crops in beds filled up. The next bed that comes out will make an opening for Seakale and Rhubarb, which is forced with less trouble in a dark shed than anywhere else. Having plenty of leaves now to mix with the stable-manure, a bed has been made up for Asparagus.

4727.—Gazianias.—I should say Gazianias might be left out in the open air in the Isle of Wight, but might get killed in the event of a very severe winter. It would be better, however, not to trust them, as they are not very hardy. The best way is to strike the cuttings in the summer and help the plants over the winter in pots. That is better than striking either early in the spring, or letting them remain in the ground through the winter. It is a pity that the bold and showy Gazania is not used more freely in gardens as an edging plant.—C. T.

Yes, I should say that these plants might be safely left out during the winter in the Isle of Wight, the soil being fairly light and well drained. They are nearly hardy, and they are generally so successfully wintered in a cold frame.—B. G. R.

I have known Gazania stand out all the winter in the West of England on a dry and sheltered border; but for the last two winters they have been killed past recovery. You had better take up some of the old plants and keep them in the greenhouse during the winter.—J. COLLINGS AT

* In cold or northern districts the operations referred to under "Garden Work" may be done from 10 days to a fortnight later than is here indicated, with equally good results.

OUTDOOR PLANTS.

MICHAELMAS DAISIES.

This year the Perennial Asters, or Michaelmas Daisies, as we like to call them, are flowering much earlier than usual, and already (September 5th) several of the more important of the earlier blooming section are in beauty. One of the best of all is unquestionably *A. acris*, which is very dwarf, quite a compact little bush, smothered with soft purple-lilac flowers. This kind is not expensive now, and it is as well adapted for the small garden or the large park, where a bed of it has a delightful aspect in the cool autumn time. It is so profuse that scarcely a leaf is to be seen when the flowers are in full perfection. Then another splendid kind is *A. amellus*, especially the variety named *bessaralices*, which, however, signifies the type. There is no practical difference between them, although it is wise when sowing for *A. amellus* to add also the word *bessaralices*, as under this name it is usually sold. This is a distinct form from *A. acris*. It is very free, strong in growth, and the flowers are large, five times the size almost of those of *A. acris*, very charming when cut, and of rich colour, deep purple-lilac, set off with orange-coloured centre. *A. alpinus* is also

is a long list of varieties, but my greatest favourite is *Apollo*, which attains a height of about 5 feet. It has broad deep-green leaves and rich-lilac flowers, measuring individually about 1½ inches across. Some little trouble probably will be experienced in getting it, although the species is common enough, but the varieties are scarce. *A. Novi-Belgi* has also given rise to a host of kinds. It is a superb type, and many of the varieties are of extreme beauty. They are worth striving to get, and I wish they were more common. The following are the finest: *Archer*, *Hind*, which is bushy in growth, with broad leaves and rose-lilac flowers, about 1½ inches across. A splendid variety is *Harpur-Crewe*, which grows between 4 feet and 5 feet high, the flowers large and white, but tinged with rose before they have lost their beauty. The finest of this section to me is *Robert Parker*. It is rather tall, quite 5½ feet in height, but one may cut down the shoots in early summer to dwarf the habit; but this is objectionable. Let every plant show its characteristic features, and this kind is spoiled when interfered with. The growth is very even, the leaves narrow, and the flowers, which are 1½ inches across, are of a lilac-purple colour. I saw a few years ago a complete collection of Michaelmas Daisies, and this variety was the

up from the border very well. It evidently loves a moist soil, but will grow fairly well in ordinary garden mould. It is not so free a bloomer as could be wished—at least, in this latitude I have never had more than a few flowers fully developed on each stem; but whether that is owing to deficient moisture or heat, or both, is uncertain, but probably of warmth. It must be propagated by seeds or cuttings. It does not divide, so far as my experience has gone. The *Romeya* is certainly a true perennial, but I do not think it can be successfully treated as a perfectly hardy perennial. But perhaps you are situated in "favoured localities in the south."—C. T.

3782.—**Lawn tennis-ground.**—You may give a light top-dressing of old decayed manure or leaf-mould, with a little lime now, but the best plan is such a case would be, I think, to pare off all the turf, dig over and manure the soil beneath, level it, then put down 2 inches of fine coal-ashes, and, finally, relay the turf. Roll it well, and there will soon be a nice sward and springy sward again. This may be done now or in the early spring.—B. C. R.

4742.—**Destroying weeds.**—The simplest weed-killer is common salt, and if the walks are dressed during a dry time the spring weeds will give no further trouble that season. It is of very little use applying weed-killers now. The rains will wash the strength away before it has any time to do good, and the chances are the edgings or hedges growier near the walks will suffer more than the weeds.—E. H.

— The best way of all is to hand-weed the walk, and in wet or moist weather the work is not difficult. This is better than applying mixtures that if your poultry are allowed a free run might result in mischief to them. Salt is a good remedy, but take care not to let it go near to the edge of the Grass.—C. T.

— By far the most innocent liquid to use for a weed-killer on paths is boiling water. When I had paths in which weeds could grow, I found it very effective, but my paths are all of cement concrete, which has the double advantage of being weed-proof and killing most of the slugs which try to cross from one bed to another.—A. G. BUTLER.

4739.—**Liming a garden.**—To secure the full benefit of an application of lime to the soil it should only be applied in fine weather and when the soil is fairly dry. If it is laid on when the ground is wet and it is moved about, the lime forms a paste and redressed comparatively useless. From 2 tons to 3 tons per acre is a suitable quantity for a heavy soil, and half that quantity for a lighter medium. The ground should be well dug up first, and then the lime spread on and forked in when the surface is quite dry. Lime is especially beneficial to old gardens, as it renders all organic matter more soluble.—J. C. C.

— The character of the soil in a garden ought to be taken into consideration in applying lime. That which is heavy in texture will require nearly double the quantity that sandy land will. For soil of a heavy, retentive nature 2 tons of lime to the acre is a good dressing, and for light land three parts of that quantity will be sufficient. The best manner of applying lime to any soil is the following: Directly a plot is relieved of the crop trench it over 2 feet deep, laying the soil up as rough as is possible for the winter frosts to pulverise it thoroughly. If the weather is dry in February, spread on the lime fresh from the kiln, that which has not been previously slaked should only be used; exposure to the air for a day or two will make any pieces crumble. If it is slaked by rain much of its strength is lost. Spread it evenly over the land, forking it in at once, but not too deep, as it is sure to work its way deeper in the soil. Lime ought not to be hurried more than 6 inches under the surface. If it is nicely crumbled when used it will mix freely with the soil as the digging proceeds.—S. P.

4760.—**A draughty corner.**—Fruit and vegetables would certainly not succeed in such a position, but you might have evergreen shrubs, Laurels, Cotoneasters, Berberis, Rhododendrons in peaty or good loamy soil, and anything you note does well in the district. It is not at all easy to advise you in such a garden, as many things that would thrive in other places would die in such a cold spot in Manchester. You might grow such shade-loving things as Solomon's Seal, Lily of the Valley, hardy Ferns, which may be all planted now, but even these will not be quite happy if the place is absolutely winless and cold.—C. T.

Flowers of a Michaelmas Daisy (*Aster amellus*).

early-flowering and called the Blue Mountain Daisy, which is dwarf, not one foot in height, and has bluish-coloured flowers quite 2 inches across, whilst those of the white variety are white. The two former, *A. acris* and *A. amellus*, are of greater usefulness, and in the garden at this season have a bright aspect, a foil to the early Chrysanthemums, White Anemones, and various kinds of perennial Sunflowers that make beds and borders beautiful at this season of the year. Beginners will select, then, *A. acris* and *A. amellus*, but for the information of those who have already got them, wishing also to add to them, I may mention that of *A. acris* there is a very dwarf variety indeed, rising a few inches above the soil, and more adapted for the rockery than any other position; it is called *nana*. Of *A. alpinus*, beside the white kind, is *roseus*, and of *A. amellus*, the dark lilac-purple variety, *amelloides*, which is about 2 feet in height, the flowers measuring 2½ inches across. Other useful early-flowering kinds that may be mentioned are the following: A beautiful variety is *A. linearifolius*, which reminds one of *A. acris*, but it is taller, and the flowers have a half-pendent character that rather enhances their beauty than otherwise. The soft purplish colour is very pleasing. *A. stricoides* var. *Glo* grows about 2½ feet in height, is bushy in growth, and produces a profusion of pale-pink flowers. *A. Lewis* is one of the most beautiful of all the Michaelmas Daisies. There

most conspicuous and lasted in perfection several weeks. *A. Shorti*, the graceful lavender-coloured, *A. tulinellus*, and *A. Nova-Angliae* deserve mention. The varieties of the last mentioned are not so numerous as in the case of *A. Novi-Belgi*, comprising flowers of various shades of rose and purple. There are many more perennial Asters, but one might stock the garden with nothing else, as it is a remarkably numerous family, will thrive in good garden soil, and if the garden is beautified with beds of Rhododendrons, plant perennial Asters amongst them. Over the shrubs they throw their graceful flower-laden shoots, and fill the garden with soft colouring in the cool, grey autumn.

C. T.

4723.—**Romeya Coulteri**—The time to plant this is in the spring, as it is not very hardy, and in hardy winters gets killed. I wish you had stated where you resided, as then one could have given better advice. The flowers are pure-white, but they appear late, and are often cut off by frost. Such a summer as the present has suited it well. In the "English Flower Garden" occurs a valuable note upon it by Mr. Thompson, of Ipswich, which may be of use to you. He says: "My experience of it leads to the conclusion that, except in favoured localities in the south, it is but half-hardy in England. It may, however, be easily wintered in a frame, and it pots

ORNAMENTAL GRASSES.

ORNAMENTAL GRASSES, both perennial and annual kinds, are worthy of more prominence in the garden, and probably others besides "G. J. H. D." would like to know which are the really good sorts. During late summer and autumn the noble Pampas Grass is assuredly one of the finest things for any garden; but even this is rarely seen otherwise than as an isolated tuft. All the nobler perennial kinds are admirably adapted for garden planting in a bold way, so that they may create an effect in the garden landscape, whilst others of dwarfier habit, together with those of annual duration only, should not be neglected. They make admirable feils to masses of bright colour, apart from their own exceeding grace and beauty.

THE PAMPAS GRASS (*Gynerium argenteum*) is without doubt the queen of garden Grasses, and all who can should find a place for it. It will grow in almost any soil, but in that which is rich, deep, and inclined to be moist, it attains its fullest grace and stature, sometimes sending up its plumes 12 feet high. It varies in height according to soil and aspect, but whether dwarf or tall is always stately and handsome. There are many forms of it, both good and bad. The finest are those that have a silky-white appearance as these when dried expand, and are so durable that I have known them to be kept several years—washed when dirty and dried again—looking fresh and new. It may not be generally known to the readers of GARDENING how the plumes—such as one seen for sale in shops—are made to appear so white and fluffy. Anyone can do it who has a good form. The plume, after being cut, must be gently shaken in front of a fire till thoroughly dried. There are several forms of the Pampas that have distinctive names, as for example Bertini, which is said to be the finest of all, and carmineum, which has rosy-tinted plumes. *G. jubatum* is a distinct species with silvery plumes, but of a much dwarfier habit. Although quite hardy, shelter from wind is desirable for the Pampas Grass, as its plumes are injured and broken down by strong winds, which are often prevalent at the time they are at their best.

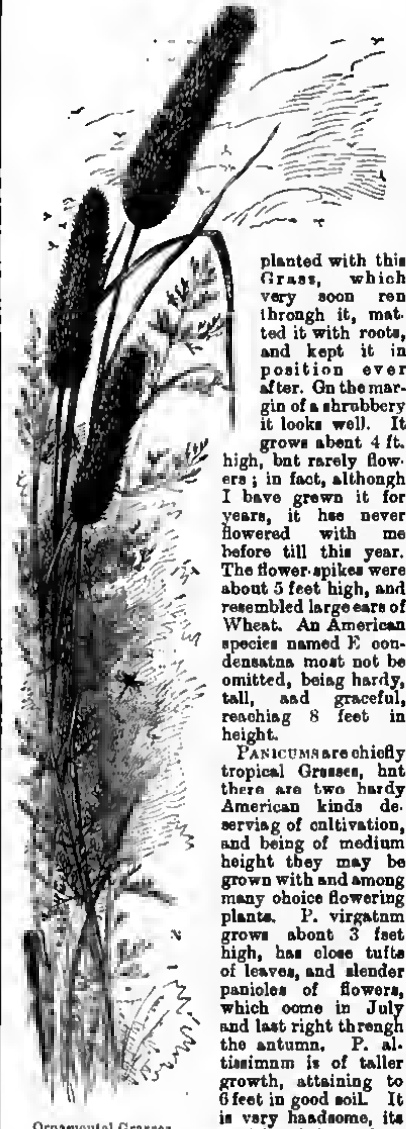

EULALIA JAPONICA is a Japanese Grass, and one of the very hardiest kinds in cultivation. If killed to the ground the crowns live, and in some parts of America where the Pampas Grass cannot stand the winter this species lives and endures through temperatures of 30 degs. below zero. Its flowers are in feathery panicles, and are of a brownish colour, but in England it rarely flowers well out-of-doors. Still, it is ornamental in the highest degree, for it sends up shoots 8 feet in height, clothed with long, graceful leaves. There are two very distinct variegated forms of it that can be recommended—one *japonica variegata*, having longitudinal white stripes down the leaf, and the other form, named *zebrina*, has transverse markings of a straw-yellow colour.

THE NEW ZEALAND REED (*Arundo donax*) should be found in every garden, being second to the Pampas in showy grace and beauty and even exceeding it in height, for in some favoured southern garden I have seen it send up its plumes to a height of 14 feet. They appear, too, much earlier than those of the Pampas Grass, often in July. Its stalks are more slender, and when well grown it is very stately and graceful. A deep, fairly moist soil is necessary to bring it to its best proportions. The Giant Reed of our marshes (*Arenaria phragmites*) is the noblest British Grass, and should be grown in districts where not naturally wild. It must be near water, however, and cannot be grouped or isolated on sunny lawns like all the other preceding kinds.

SACCHARUM Aegyptiacum is a striking and very uncommon Grass. It is a native of Africa, and requires a deep, warm soil. It does not flower in this country—at least, not outside—but it has tall, slender, Reed-like stems, clothed in graceful leafage, and attaining from 8 feet to 10 feet in height.

Elymus arenarius, otherwise known as the Sea Lyme Grass, is a British plant, found abundantly on some of our sandy shores. Although not wild inland, it is very bumpy in any garden, and apparently does not mind whether it is planted in clay or sand. It is entirely of a rich, glaucous green, very beautiful

in colour, and rampant in growth. It spreads freely, and should therefore not be planted in beds or borders of choice things. I once had a bank of loose, light soil that was always giving way and rolling down on the path. It was

Ornamental Grasses.

APERA ARUNDINACEA is a slender-growing but most elegant Grass, quite one of the choicest. It is sometimes called the Pheasant-tail Grass, owing to the length and gracefulness of its plumes, which are of a brownish tint distinct and showy. It has hash-like leaves. Beautiful as it is in the garden, there are few more useful Grasses for cutting, its plumes lasting for a very long time. Last, but far from least, comes the

FEATHER GRASS (*Stipe pennata*). It is a perennial worth growing in association with flowering plants, close and tufted in habit, barely exceeding 1 foot in height, but constant and profuse in bloom; the flower-spikes long, narrow, foother-like, and most graceful. There are other perennial kinds, such as Sorghum, the Aarepogona, &c., but these mostly want light, warm soil. The selection of perennials here given comprises the best. The annual kinds are very numerous, and some of them are delightful things for cutting, whilst all are of easy growth, if sown in rich, friable soil out-of-doors. One rarely sees them associated with flowers in the flower garden, but they may be used prettily in this way, whilst for cutting they are very valuable. In summer the lovely panicles arrange well with flowers, and in winter, along with Everlastings, they are most useful for permanently

filling vases when flowers are scarce. With these Grasses in the garden, Maiden-hair and other Ferns are not quite so essential. It is too much the rule to think there is nothing like Ferns for arranging with flowers. As there are noorly fifty kinds alone among annual Grasses, it is necessary to make a selection for so many are not generally wanted.

AGROSTIS NEBULOSA is a charming Grass, light as the air, and elegant beyond description. Words cannot describe its effect when in flower, and nothing could be nicer for cutting or drying. *A. pulchella*, of dwarfier habit, is also desirable. *Briza maxima* and *B. gracilis* are two distinct kinds, resembling our native Quaking Grass, but one larger, and the other smaller, both free and of easy growth. *Bromus briziformis* is by far the best in the large genus to which it belongs. It is tall and graceful, with large branched, drooping panicles, and is first-rate for drying. It should be treated as a biennial, by far the best results coming from autumn sowing. If treated as an annual it should be raised early in pots, and planted out as soon as ready. *Eragrostis* or Love Grass is soft and graceful. There are several species, but elegans and aegyptiaca are the most distinct, especially the last named, which has silvery-white plumes. *Hordeum jubatum* and *Lagurus ovatus* are entirely of different character, having close heads. The first is known as the Squirrel-tail and the last as the Horse-tail Grass. Both are pretty and desirable.

LEPTOCHLOA GRACILIS is a free, easy-growing kind, profuse blooming, with a slender branched dark-brown panicle. *Pennisetum longistylum* is very attractive, the flowers having long hair-like styles projecting from a twisted downy head of a dark-purplish colour. It is easily grown as an annual, but is quite a perennial on some soils. It grows about 18 inches high.

PIPTATHERUM THOMASI is a tall, graceful Grass that I noted last season in Mr. Barr's nursery at Long Ditton. It has enormous long panicles of bloom, the branches being in whorls of eight or nine, and separate from each other, making the panicle long, open, and strikingly pretty. *Tricholena rosea* is also very pretty, tall and slender, its panicles, as implied by the name, being tinted with rose. These are the best annual kinds that have come under my notice. It would be easy to add to the list, but the most useful and most distinct are named above. A. H.

4735.—Cornflowers.—Autumn sowing produces the strongest plants, but the plants in spring will flower the same time as the Roses. It is too late to sow now anyway.—E. H.

—It is rather late to sow now, but if the early part of the winter proves mild, seedlings started now would probably survive, and such would flower both earlier and better than others not sown until the spring, especially if the soil is very light and warm. I should certainly choose a moderate sowing now, and get some more seed in in February or March.—E. C. R.

4725.—Braeken on pasture-land.—This may be got rid of by constantly cutting it down. It will take time, doubtless, so will any other method. No plant can live long, which is not permitted to make top growth.—E. H.

—If you persevere in cutting the tender tops off directly they appear above ground, in the course of a year or two the roots will die away, and give no more trouble. This is the only way, for to dig out the roots would be an endless job.—E. C. R.

4767.—Dwarf blue-flowering plants. —I can quite sympathise with you in regard to Lobelia. It is very pretty when you are close to it, but makes no show at a comparatively short distance. *Violas Freedom* or *Blue Bell* would have a far more striking effect. Most flowering plants, such as *Campanulas*, bloom only for a limited time, otherwise they might answer your purpose. Next to the *Viola* the most effective and continuous blue-flowering plant I know is *Convolvulus minor*, but it becomes straggling and untidy towards the end of the summer. If purple would satisfy you I should recommend *Verbena peggadown*; nothing could be neater or prettier.—A. G. BUTLER.

—One of the very best plants for the purpose would be the *Bine Daley* (*Agathoa cuculotia*). It is of dwarf compact habit, most profuse, and constant in bloom, and decidedly a pretty thing. It could be purchased cheaply next season about the usual time, and afterwards stock can easily be kept by taking cuttings, which root easily in September in a cold frame kept close, and the plants will winter well in any frost-proof structure.—A. H.

CHRYSANTHEMUMS.

**SEASONABLE NOTES ON CHRYSAN-
THEMUMS.**

THE continuous damp weather of the last week will tend to crasto the early decay of the first-opened blooms if they are at all neglected in the matter of supplying them with air in sufficient quantity, accompanied with a slight warmth in the hot-water pipes to caase a haoyancy in the air. It generally happens that the amateur's greenhouse or vinery is stuffed full of plants along with the Chrysanthemums that he cannot dispense with. These require water as well as the Chrysanthemums, the whole tending to make the inside of the house heavy and moisture-laden, if all favourable opportunities are not seized to throw open the ventilators wide during the day, when the sun shiocs brightly, and there is not much wind blowing. I am not, however, in favour of admitting direct draughts of cold air to reach the plants when the flowers are developing, especially should the wind be blowing from the east. When the wind is in the south or the west the air is generally warm at this season; fire-heat is not at all necessary then during the day, provided the hnoyancy is kept up by the aid of the sun. It is, however, wise to have the assistance of warmth in the hot-water pipes during the day in dull weather. The air is very often laden with moisture, so that a little artificial warmth dissipates condensed moisture, to the benefit of not only the opening Chrysanthemum blooms, but to all other occupants of the greenhouse or vinery. Any watering required ought to be done in the morning so that the floors and paths are quite dry before nightfall. The constant removal of dead and decaying leaves helps to maintain the air in a sweetened condition. After a few days of continued dull weather the blooms are very subject to damping or scalding upon the first burst of sunshine. The latter, perhaps, is the correct name to apply to blooms that are spoilt in one day, as is very often the case when the plants receive no shade whatever after a few days of dulness in the weather. Some tiffany stretched over the glass outside will generally provide sufficient shade and prevent the blooms being injured through that cause. When the blooms are three parts expanded feeding may cease; it is useless to expect that the continuance of stimulants will benefit the plants after that stage. When the blooms are fully developed they will keep fresh longer if the soil is kept rather on the dry side than otherwise. During dull weather, if the soil is constantly wet, the plants do not absorb it in the same ratio as when growth was at its height, or even when the blooms were expanding. Consequently the sluggish roots create what is known as "spot" in the petals. At first it is represented by a tiny dust-like speck on the surface, but it gradually increases until it is nearly the size of a small pin's-head, and, of course, disfigures the blooms beyond recovery. When blooms are attacked in this manner it is not simply one or two petals, but the whole bloom is similarly affected, so much so as to render it quite useless. Greater attention to the state of the roots and the maintenance of a hnoyant atmosphere will do much to prevent the spread of this maledy.

E. M.

474d.—A white Chrysanthemum—This is evidently a white "sport" from the typical variety, and if it proves to be constant or "fixed," it will be a most valuable novelty. You may either raise a stock of it yourself first (taking the cuttings only from the shoot or shoots bearing the white flowers) or else dispose of the plant as it stands. I have no doubt you will easily obtain a good price for it either way from any of the large and well-known Chrysanthemum growers.—B. C. R.

—There is a white sport of Viviani Morel—at least, so called, but I really doubt it. You may get the flowers of Viviani Morel white on the early crown-bud, the flowers coming quite pure. I was interested recently in seeing a very fine collection of this Chrysanthemum in full bloom, and the diversity of colouring was most conspicuous. The true colour is a deep-lilac and flowers of this tone are produced on late buds, but those on the early crown-buds were

absolutely colourless. The question you ask has given rise to much discussion. Some aver that there is a white sport, some not, so one is a little perplexed to know who is correct.—C. T.

—No Chrysanthemum that I know is so variable in the colour of its blooms as Viviani Morel, caused simply by the different stages and times that the buds were formed. Those taken in July invariably produce white flowers, the next pale-pink, and those that are taken from the middle to the end of August give the colour that is the most pleasing, and which renders this variety so valuable as an exhibition flower. So numerous are white blooms from this Chrysanthemum this year that it will be necessary to further test the plants another season before finally deciding the matter. If cuttings taken next December from the plant that produced the white blooms this season, grown on the large-bloom system and as bushes also, give white flowers, then you may reckon upon having produced a real White Viviani Morel. A second season is necessary in all cases to test any supposed new variety the result of a sport before being certain that it is distinct.—E. M.

LATE CHRYSANTHEMUMS.

THESE very useful plants are now filling up their flower-buds, and require a liberal supply of liquid-manure to enable them to develop a full crop of blossoms. Unlike the exhibition varieties, there is no need to produce monster flowers, but rather to obtain a good supply of those of fair medium size, and to do this large bushy plants are required to produce one good bloom at the end of each side branch, so that only moderate disbudding is needed, and some kinds do not require this done at all. The season has thus far been favourable to their development, where artificial watering has been carefully attended to. I grow a good many plants in large pots, and they are now covered with large plump buds, and in addition I grow a large quantity planted out. They are struck from cuttings in March, and planted out in rows on good soil, like Cabbages, about 2 feet apart, and pinched back once in May and then allowed to grow unchecked, each plant being loosely tied to a stake as they progress to growth. About

A Golden Maiden-hair Fern (*Adiantum sulphureum*).

the end of October they are lifted with good balls of earth and transferred to the floor of a vinery when the fruit has been cut, planting them in the soil, and giving copious supplies of water until the blooms begin to expand, when they are kept as dry as possible, with plenty of air, and by this means I get as good a supply of Chrysanthemums at Christmas and New Year as in any part of November, and they are in much greater demand.

J. GROOM, Gosport.

Plants for next year's bloom-
ing. You have left it too late to sow seed of plants mentioned now. This should have been

done in April, May, or at the latest in June, in order to obtain strong plants that will bloom well next summer. They should be fit to plant out now, and if a display next year is an object the best course will be to purchase plants. Raising the plants is a simple matter enough. The best way—at least, in the case of all those with fine seeds—is to sow in shallow boxes in a cold frame, pricking the seedlings off into well prepared nursery beds when strong enough, and finally planting them out permanently in October. Pentstemon seed may be sown in heat in February, and with liberal culture most of the plants will flower towards the autumn.—B. C. R.

FERNS.

GOLDEN MAIDEN-HAIR FERNS.

THIS popular genus of Ferns includes a few species which are ornamented with a farious powder similar to that family of Ferns so well known as Gold and Silver Ferns (*Gymnogramma*). The two kinds named here are exceedingly beautiful, but very distinct, and are well deserving the attention of everyone possessed of a fernery or Wardian-case. There is nothing exceptional in the treatment of these two species; those who have the common Maiden-hair Fern (*A. cuneatum*) doing well may hope to be equally fortunate with these.

A. sulphureum.—This is a charming small-growing epiphyte, which was originally introduced from Chili by the Macrae Backbones, of York. It is usually considered a difficult plant to manage, but this arises, I imagine, from its being kept too warm; our illustration was taken from a plant which grew in the open air during the summer, but the plant suddenly disappeared, so that the opportunity of testing its hardiness was lost. The fronds vary in length from 4 inches to 1 foot, they are three times divided (tripinnate); the pinnules when infertile are roundish, but when fertile they are obovate, uniform, furnished with copious sori, and clothed on the underside with a dense, shining golden-yellow, farious powder.

A. WILLIAMSII is a more robust-growing plant than the preceding; it has been introduced from the mountains of Peru by Mr. Williams, of Upper Holloway. It is said to have been found growing at an elevation of some 12,000 feet; consequently it thrives admirably in a cool fernery; indeed, the golden farina with which the atoms and underside of the fronds are powdered appears to remain longer upon the plant under cool treatment than when grown in stronger heat. It appears to be as free in growth as *A. cuneatum*; the fronds are from 12 inches to 18 inches long, light and graceful, and admirably adapted for cutting. G.

**THE HOLLY FERN (POLYSTICHUM
LONCHITIS)**

"J. KINNARD" sends some fronds of this species which he has collected in Switzerland, asking its name, and saying that he has never seen it in England? The vernacular name as well as the scientific one is here given, and I am glad to inform my friend that it is a British plant, and that it is found in many parts of Britain—for instance, near Ingleborough in Yorkshire. It is also found in the North-west of Ireland in several localities, also on the mountains in the Highlands of Scotland, and on the mountains in North Wales, so that it may claim to be a genuine British Fern. It is found more plentifully in various parts of Europe, and my friend "J. K." says he had found it to grow plentifully in the mountains of Switzerland, and my friend will find this is only to be found at considerable elevations, and I do think it is a plant that will not thrive well except when the soil is well intermixed with limestone, and when planted in this I have only been able to keep it grown in a pot, and under cover in a cool-house. I have never had this Fern grow well in the open ferneries for more than two years. Some friends, however, assured me that they had the same plant for a great many years growing upon their fernery, but upon my calling to see them one day and asking to see the Holly Fern, I was coolly shown a plant of *P. aculeatum*, which I was told had been developed from a plant of *P. Lonchitis*; but as I was quite aware of how this development comes about, I had to

undecieve my friends, and I at last succeeded in doing so. The fact is, that in the young state the species *P. conlactum* assumes somewhat the guise of *P. Lonchitis*, and may be mistaken for it, and I would like to caution my readers against purchasing plants of the so-called Holly Fern from any of the plant-bawkers in the neighbourhood of London, at any rate. The right plant is a beautiful evergreen species, making fronds from 5 inches to 20 inches high. These are but once divided (simply pinnate), the pinnae undivided, epiny at the edges, and deep-green on the upper side, paler beneath; the rachis is densely scaly. It is not a species that appears to vary much, but there are two or three named and tolerably well-developed varieties known, such as *P. Lonchitis* var. *oristatum*, *P. Lonchitis multifidum*, *P. Lonchitis proliferum*, and some others. J. J.

4755.—**Scale on Ferns.**—The best way to get rid of this pest is to sponge the affected parts rather heavily with warm water in which some soft-soap and a very little paraffin has been dissolved, and afterwards with pure water. If you "dry off" seedling *Begonias* just up you will never see them again. Keep them growing on quietly in a warm-house or pit near the glass until as late as possible, when each will have formed a tiny bulblet. These must be kept moderately warm, and neither wet nor dry through the winter, be started in growth early in heat, and when in growth be first pricked off and then potted singly.—B. C. R.

Young Ferns are wonderfully cheap now, and wherever the plants are infested with scale gather them together carefully, and burn them. This is the most economical course to take. Afterwards clean the house with soap and water, and get a fresh stock of young plants. The *Begonias* will have scarcely formed tubers yet, and therefore must be kept moving slowly all the winter, as there is nothing to dry off.—E. H.

ORCHIDS

MILTONIA VEXILLARIA RUBELLA.

This is a variety of the species and is remarkable for its great variability in colour and in size; and in the flower sent by "T. II.," I see the bloom much reduced in average size. The colour is rich and bright, and this form was, I think, first introduced to notice in English gardens by Mr. Wm. Bull, of Chelsea, but I do not remember at what date. However, it is just twenty years ago that the first specimen of the typical plant flowered in the nurseries of the Messrs. Veitch and Sons, of Chelsea. It is an Orchid which appears to have a somewhat wide distribution in New Grenada and on the mountains in Ecuador, but not occurring at such an elevation as do *Odontoglossum Penicillatum*, or the Princess of Wales' Orchid, named by Bateman O. Alexandre, but which more recent authorities have generally agreed is the same plant to which Lindley had previously given the name of *O. crispum*, and, consequently, it does not thrive in so low a temperature as does that popular species; but of the precise locality whence this variety was originally collected no records are kept or known, saving by the actual collectors; but still I do think that the variety *rubella* must grow at a greater elevation than the usual run of the plants, which are said not to occur at a greater altitude than about 6,500 feet, and not lower than about 4,000 feet above the sea. It is an Orchid that varies much in size and in the depth of its colour, but all are beautiful. But I think the variety here spoken of is about the smallest form that I have seen; but they are of a good deep rosy-pink colour. This colour, however, becomes much paler towards the edges. Since I received these flowers I have had a run out and visited two or three collections of Orchids; in one of these I saw one or two examples of the variety called *apertha*, which has a large triangular blotch upon the lip of deep blood colour, just coming into bloom for the second time this season, and this, I used to think, was amongst the smallest-flowered kinds; but now I must alter my opinion. In speaking of the variability of the colour some time ago with Mr. Deane, of St. Albans, and saying that his were very rich in colour and large in size, he remarked, "Yes; these plants

come from a new locality, which appears to yield much finer and richer-coloured varieties than the old and better-known spots where it has hitherto been collected." But he did not say if the plants came from Columbia or from Ecuador. I do not like this plant to be in a lower temperature than 60 degs. during the day, but this may fall to 55 degs. during the night or in the morning, and the thermometer may rise to nearly 80 degs. in the summer-time with sun-heat, without causing any ill effects; but during this time the plants themselves will require a great deal of water to their roots, as well as a very liberal amount of moisture in the atmosphere, and a due amount of ventilation, for it should be borne in mind that if this is not well attended to the plants will become infested with black-thrips, which is their very worst pest; so let the pots be well drained, and the plants be potted in a mixture of good brown fibrous peat and chopped Sphagnum Moss. This should be pressed down firmly, and be surfaced with some of the most lively pieces, so that it will grow and make a nice pleasant appearance, and this makes a nice soft and cool bed for the roots of the plants, and at all seasons of the year the air should be kept moist, for in what is called the dry season in their native country rain enough falls to maintain a constant humidity in the atmosphere. MATT. BRAMBLE.

TREATMENT OF ODONTOGLOSSUMS.

"ARTHUR EASTON" asks how he is to manage some half-dozen species which he names, and which he says are kept at from 45 degs. to 50 degs. in the night-time from about the beginning of December till the end of February? This is quite hot enough for them at this time, and although I do not advise you to keep them dry at such times by any means, less water must be given them, because they do not require any resting season, and the *Odontoglossum macranthum* may be treated in an exactly similar condition, and all these plants like a shady situation; but the *Coelogyne cristata* does like more sun, and a little more heat during the growing season, and after its tubers are made up. As regards the ventilation of your houses, these should be fitted up so as always to have some air running through the place; but less should be left on in very cold weather. If expense is no object, however, you may keep a good round amount on the house or houses nearly at all times, simply making up any deficiency in the temperature by extra fire-heat. This system, however, is fraught with more bad results in the cool-house than with other houses in the matter of watering. Although I frequently make use of the expression plenty of water, I do not mean that the plants are to be treated as aquatics, but the soil is always to be kept nicely moist, and without a shade of dryness. I hope you will succeed. MATT. BRAMBLE.

ONCIDIUM INCURVUM.

This is the name of the spray of flowers sent by "James Mookings." This plant sometimes goes by the name of *O. albo-violaceum*, but the name given above is the correct one. It bloomed in Birmingham for the first time some fifty-three years ago. It is quite of an unusual colour amongst *Oncidiums*, for in this family yellow of some shade is the prevalent colour. The plant has flowers each about an inch across; and the sepals and petals are white or pink, spotted and tipped with white; the lip is white; the crest in some varieties is clear yellow, but in the one before me it is of a pale lemon colour. This is the typical form of the plant, but some few years since we were all astonished and surprised to find a pure white-flowered kind crop up. The first time I saw the plant was some few years ago when travelling in France. It is about the normal size, having pure white flowers and a yellow crest, which saved the plant from being passed over without notice, for I have a great dislike to a pure-white Orchid flower without the least bit of colour to relieve it; but, thank goodness, there are very few that are wanting in this respect. As to the management of this plant, it is a native of Mexico, at some 4,000 feet or 5,000 feet elevation, and therefore it requires cool treatment; indeed, it will thrive in the warmest end of the *Odontoglossum*-house at the season; but I like to keep it some 50 degs.

warmer than this during the winter months. The plant succeeds best potted in good brown peat-fibre, mixed with Sphagnum Moss, and a few pieces of sandstone in the soil is no hindrance to the plant's well-being, as it keeps the soil more open and drains the soil, which this plant likes, for although it requires plenty of water and a cool, moist atmosphere, all stagnant and sour water or soil should be carefully excluded from about it. MATT. BRAMBLE.

LENTEN ROSES (HELLEBORES).

MANY only grow the varieties of the true Christmas Rose, forgetting or not knowing that there is quite as beautiful a race that blooms in the spring months onwards towards summer. These are commonly known as Eastern Hellebores, or Lenton Roses, and from their wealth of foliage and charmingly coloured flowers give interest to the garden. Few seem to think of the foliage of the Hellebores, which is bold and luxuriant in such species as the native *H. fetidus*. A fine effect is made in winter or early spring by large clumps of common *H. fetidus*, the leafage very leathery, much divided, and of a profound green colour, in rich contrast to the greenish-yellow flowers. It grows well in ordinary garden soil, and is best planted in groups in the border, or higher parts of the ruckery, or in front of shrubberies, where it is in keeping with the surroundings.

THE EASTERN HELLEBORE (*H. orientale*), a native of Greece and Syria, is a very beautiful species with fine foliage and whitish flowers that are produced on slightly bent stems, very graceful in effect. But much has been done by hybridising it with the forms of the Christmas Rose and other types, so that we get a delightful series of varieties, the flowers bold and variously coloured, some quite white and very pleasing against the green foliage. Some of these forms are named and catalogued as *H. orientale strabus*, and *H. o. lividescens*. Good ones should also be made in groups of *H. olympicus*, so named from its native home, Mount Olympus, in Greece; the flowers of a whitish colour, but varying in shade. Very beautifully spotted are the flowers of *H. guttatus*, the inner face of the segments dotted with purple; and from this type many excellent crosses have been made with other kinds, resulting in a delightful series of spotted forms, the colour distributed both in dots and suffused over the flower. Many of them have been given distinctive names, but there is danger in this practice, unless they are amply distinct, as considerable resemblance exists among them. A handsome species is *H. colchicum*, the flowers crimson, but varying in shade, and between this and other types many beautiful hybrids have been raised. The species is of strong, bold growth, the leaves divided, toothed, and of a very deep-green colour, almost purplish in their early stages. A well grown plant is an object of much beauty, broad, very deep in colour, and vigorous, whilst in March or earlier, if the weather is favourable, the flowers appear. *H. abchasicus*, which grows about the Black Sea, is a pleasing species, the flowers very dark purple, especially to the bud, but changing with age to a duller tone. *H. atro-rubens* has also purplish flowers, but some of the hybrids from this and other kinds are the more beautiful. Some of the crosses with *H. guttatus* are unique in colouring, the flowers much spotted, and finely suffused. When referring to

H. fetidus, the best positions for these species and hybrids were indicated—viz., in colonies or groups by the margins of shrubberies, or in the border, and with deep-green leafage as a relief the crimson-flowered kinds are very distinct and handsome. Although good garden soil will suffice, it must be thoroughly well drained, as one of the great evils to contend against is stagnant ground. Some amount of shade is desirable, but often a very poor result occurs through planting in borders near hedges or large shrubs and trees which have sent their roots into the soil and extracted most of the goodness from it. One cannot expect a vigorous growth, a full display of flowers, and broad ample leafage, which is one of their chief glories, under such conditions. By having a well-prepared soil to commence with, well dug up and manured, it will not be necessary to disturb the plants for many years. F. P.

THE KITCHEN GARDEN.

KITCHEN GARDEN NOTES.

THE shortening of the hours of sunlight remind us that preparation must be made for winter before it is actually upon us, and this year there is especial need for making the most of the few weeks that intervene between summer and winter, as the drought was so protracted as to render a good many operations almost impossible while it lasted, but now that copious rains have at length fallen, no time should be lost in pushing on all kinds of ground work. Amongst the most pressing work needing immediate attention, I will direct attention to the work of

CABBAGE PLANTING FOR SPRING.—Presuming that a good supply of plants is available, the soil intended for the beds should be liberally manured and deeply cultivated, then set out in rows 2 feet apart and put the plants in about the same distance apart, pressing them very firmly into the soil, and after a fortnight's interval run the hoe between the rows, and a few days later draw a little soil up to the stems of the plants, so it supports them against wind-waving and keeps the frost from affecting the stems. Cauliflowers of the Autumn Giant kind are now coming fit for use, and should be frequently looked over, breaking the leaves down to protect the white heads from getting discoloured by exposure to sun or wind or the action of frost. Young plants of Early London, and other kinds for first crop next season, should now be pricked out in hand-lights or cold frames, keeping them well ventilated in mild weather so as not to excite growth too much.

CELERY.—Late crops will now need attention in the matter of earthing up, the early crops being now fit for use. As a rule, Celery is not a good crop this year, except where extra care has been given to watering, as being a very moisture-loving crop the dry summer and autumn acted very adversely on its growth.

LETTUCES should now be planted out on a sheltered sloping borders where they can be kept free from stagnant moisture during winter, and a good supply of young plants should be placed in cold frames in case of a severe winter cutting off the open-air stock.

POTATOES should be all lifted by this time, as nothing is gained by leaving even very late sorts in the open ground after the heavy rains have saturated the soil about them. All those that were lifted early will need careful looking over, for if at all thickly together they will be liable to start prematurely into growth, and thereby spoil the quality either for culinary purposes or for seed.

TRENCHING up all vacant soil should be done at this time of year, so as to get it as much exposed to the winter frosts as possible, and also to avoid a **pram** of work in spring. All

FRUIT TREES should be pruned as soon after the fall of the leaf as possible, and those on walls should be nailed to the wall, and espaliers should have the stakes made good and neatly tied. This is the best time to wash the trees with insect destroyers.

WINTER CUCUMBERS.—These will require much attention now, and especial care should be taken not to overcrop at first, so that the plants may have strength to go through the winter well and bring a full crop of fruit when needed. Of course, a well-constructed house is required with ample means of heating. A fine winter crop of Cucumbers is shown in the annexed illustration. Two of the best kinds to grow for winter work are the old true Telegraph and Lookie's Perfection. J. G., *Hants.*

you as much as anything. It is possible that the gas-lime may have lost some of its power before you need it, but you must understand that it cannot be applied in sufficient quantity to destroy such insects as wireworms without injury to the crops. If those who are daily witnesses of the formation of gas-lime, and who ought to know something of its destructive quality, if any, are to be relied upon, it appears that it is of no use whatever to place upon the land, although the vendors of it will not tell purchasers so, as they want to get rid of it. Anyway, I know that a sort of covert smile passes over their countenances when they see the useless stuff leaving the premises.—J. C. C.

MAKING A KITCHEN GARDEN.

IN the formation of a garden of this kind mistakes are often made, and if care is not taken the soil may remain comparatively sterile for two or three years. It appears a very easy matter to form a good kitchen garden out of such a site as a Grass field, all that appears

with those on well-drained ground. It therefore behoves those who may have the formation of a kitchen garden to first see to the drainage. The carrying out of such work need not be referred to in this article, as the formation of the ground decides such work. Drainage, however, must be well done, so that the water can have a free course. The work should commence now, so that the turf can decay before cropping takes place in the spring. Not that general cropping is the best for the first season at any rate. A crop of Potatoes is the best the first year, this getting the soil into good order for the following season's cropping. At any rate, early Potatoes might be planted, and these could be got off in time to allow of the planting of winter vegetables. All these things have to be taken into consideration, as very often people with limited experience are under the impression that the soil can be quickly got into condition for the reception of quite small seeds. Whether manure or other correctives should be added at the time of trenching will, of course, depend upon circumstances. It is plain that anything which would tend to improve the working of the soil, and also its fertility, will have its due effect upon the crops which will follow. If the soil be clay, anything which could be added to ensure its free working will certainly be of great benefit, as very often such soils are often incapable of producing the crops they should account of being too heavy. As we all know, a free use of manure is of great advantage; so also are burned or charred soil, garden refuse, and last, but not least, road scrapings. This last is a capital corrective where good material can be had, as besides containing a fair percentage of horse-droppings, it is also composed of a fair percentage of gritty matter, which tends to keep the soil open. How it should be used will, of course, depend upon the quantity at disposal. When there is plenty of any of the materials mentioned, one and all may be worked into the soil as the work proceeds, leaving a fair dressing of the best, such as

DECAYED MANURE AND REFUSE, for forking into the surface in the spring. If by chance there should be very little, and manure in particular, it had much better be reserved for working into the surface in the spring, as to add to the surface fertility for the immediate benefit of the crops which may follow. By commencing the work now the decay of the turf will commence, and the surface be opened up to the winter frosts and snow, so that all will be in readiness for spring cropping. What has to be considered at the present time is the keeping of the most fertile soil at the top and the burying of the turf sufficiently deep to cause decay, but not yet too far from the surface, although deep enough to keep it from growing through. What is known as bastard trenching is the best to adopt, although it will differ slightly on account of the growing turf. In the ordinary course of bastard trenching the top soil in its entirety is kept on the surface, the bottom being forked over, at the same time adding manure. Any attempt at deep trenching, such as the old system of three spits, turning it upside down, would only result in failure, and very likely, as previously hinted, would make the surface soil sterile for some time to come. In commencing the work take out a trench 3 feet wide, as there is nothing like having ample room for working, cramped trenches preventing the work from being carried out expeditiously. The turf should be taken off first to the depth of 2 inches, not more, and, of course, it will be the same with each succeeding trench. Now take out a good spit of the top soil, and take this and also the turf from the first trench to where the work will finish. The bottom soil should now be forked over, adding the correctives and also the top turf of the next trench, and on to this place the next spit of soil, which, from being immediately under the turf, will be in a fertile state. The

OUR READERS' ILLUSTRATIONS: A good crop of Cucumbers. Engraved for GARDENING ILLUSTRATED from a photograph sent by Mr. Isaac Bteley, Mount Pleasant, Hazel Grove, near Stockport.

necessary being to trench it over, placing the top spit at the bottom of the trench and the bottom at the top. Now this is where the mistake is made, for unless the ground should be naturally good to a fair depth, this turning of the soil upside down to the depth of 18 inches or 2 feet may end in failure. What is wanted is a fair depth of fertile soil. Decaylug turf, as all gardeners know, is a storehouse of food for growing crops, although in this respect it is not always a universal blessing, for often it is the home of root-eating insects, particularly wireworm, which is often to be found in new gardens formed from Grass-land. In the first place, it must be seen whether the land requires draining, as it is better that this should be done before the soil is disturbed.

DRAINAGE plays an important part in the well-doing of crops. Land that is ill-drained will never produce satisfactory crops, as besides keeping the soil in a cold state through its water-logged condition, it prevents that aeration so necessary for the well-doing of the different subjects that it will be called upon to produce. It is surprising how backward the crops are on these cold, undrained soils when compared

4775—**Cabbages clubbing.**—There is no known cure for the injury done to your plants by the insects which cause the clubbing of which you complain. The withholding of manure will not help you. Dressing the ground with soot when it is fairly dry is as likely to help

work should be carried on in this way until the whole is finished. By the following spring this top soil will be well broken down, and into this should be lightly forked the manure and burned refuse. If it could be so managed to crop it with Potatoes, it would be all the better for the succeeding crops.

POTATOES CLEAN THE SOIL, and the planting, hoeing, mounding-up, and so forth get the soil

Fig. 1.—Early Turnip "Snowball."

into good working order. If the whole could be turned over again in twelve months' time, there would be a good depth of pulverised soil. If any constituents, such as lime, should be lacking, these could also be added. As regards the preparation of the soil for the orchard, it will depend entirely upon the class of trees it is intended to plant. For instance, if the orchard is to be on Grass and the trees which it is intended to plant are standards, then only stations need be formed at the distance apart decided for the trees. On the other hand, if the orchard is to be mixed and to include small fruits as well, then the whole should be treated as I have advised for the kitchen garden. Stations for standards are generally formed about 6 feet over, and to the depth of 18 inches or 2 feet. The whole of the soil should be taken out, taking care when it is returned that the good soil is kept on the surface, the turf being placed just beneath the roots. The turf as it decays will feed the roots, as if placed too far down and the subsoil should be of an indifferent description, it is apt to attract the roots downwards. If any correctives are needed, they should be added at the filling in. Y.

TURNIPS (EARLY AND LATE).

It is surprising to note in different parts of the country the varieties of Turnips grown and the qualities of them. Yellow-fleshed Turnips are popular in the north, and I have often seen there splendid examples of good culture. I have heard it stated by our leading seedsmen that in private gardens there is but little demand for the yellow-fleshed varieties of Turnips. As is well known, the old Orange Jelly or Golden Ball is one of our best kinds for standing late. I always sow a few rows of Golden Ball and Chirk Castle for winter use, as, should the weather be severe, if not sown before the middle or third week in August, they do not get too large, and a small Turnip is better and resists frosts and gives a lot of greens in the spring months better than a late one. I think one of the best Turnips ever sent out is Veitch's Red Globe. This is not one of the earliest, but it is the best for general crop, as it remains good longer than others of handsome shape, and it is also very hardy. It will also be found useful as a garden variety when required for early work. Those who have a difficulty to get Turnips on account of their running to seed should, at the time of sowing the early kinds—such as Early Milan or Snowball (Fig. 1), an excellent kind for frame culture, as is also the "Jersey Navot," or Forcing Turnip (Fig. 2)—take the precaution to sow a few rows of Red Globe, and there, though a few days later, will often succeed when the earlier ones fail, as it

frequently occurs that the first sowing on some soils is anything but profitable. I have adopted this plan for years. As a late Turnip for storing for winter use it is one of the best, and an excellent keeper if nice sized bulbs are stored. For forcing in frames, the Early Milan is excellent, of quick growth, and good flavour, but as many cannot afford room for these, a late sowing of Red Globe, if stored in soil, sand, or ashes in a cold place, keeps well into the spring. With a small sowing of the late kinds no difficulty will be found in keeping up a supply all the year round. G. WYTHES.

LATE TOMATOES.

THIS has been a splendid season for Tomatoes, as they delight in plenty of sunlight and a dry atmosphere, and seldom have we had such fine ripe crops out-of-doors, not only on walls, but right out in the open—in fact, those against walls, unless well supplied with water at the roots, did not, with me, produce such heavy crops as those in the open, from the fact of the soil close up to the base of sunny walls getting too dry even for Tomatoes, unless water was supplied artificially; and not only have Tomatoes produced such fine crops, but they kept so free from disease that they have continued to grow on and produce successive crops that they look as if they would continue bearing up to Christmas, if the dreaded frosts would keep off; but as we cannot expect these late fruits to come to maturity out-of-doors it is advisable to cut off all the fruit that are coloured and place them under glass to finish off their ripening until required for use. This will throw the strength of the plants into the latest fruits, and if they can be left on the plants until they get fully grown, even though they are not coloured, they will be very useful for culinary purposes, if the stalks of the plants are cut with the fruit hanging on them, and after cutting off all the foliage, hang them up in any glass-house to ripen. J. G., Gosport.

4750.—Sweet-scented Carnations.—Countess of Paris is sweetly scented, but I am afraid none of the others mentioned are in any degree. Your question is most interesting, as fragrance is too much left slight of in the Carnations, as in the newer Roses, in many cases, whereas the fragrance should be one of the chief features. A Carnation without scent is worth little. I do not care for such flowers, although they may be beautiful in form and colour. A Rose, for instance, without fragrance is bereft of its sweetest charm.—C. T.

4769.—*Tropaeolum speciosum*, &c.—*Tropaeolum speciosum*, plants or root-cuttings, cool, moist position; *Spiraea astilboidea*, plants, moist, lightly shaded spot; *Harpallium rigidum*, division, sun or shade; *Trollius dahuricus*, division or seed; *Gaillardia*, cuttings or seed, sunny position, and light soil; *Cactus Dahlias*, cuttings, rich soil; *Funkias*, division, ordinary culture; *Romneya*, ditto; *Lobelia fulgens*, division, rich, moist soil; *Perennial Sunflowers*, same as *Harpallium*. Nearly all these are best planted in the spring, about April.—B. C. R.

The *Tropaeolum* mentioned requires a moist, cool soil and position. It will not succeed in hot or dry spots, and the best place for it is against a hedge, through which it sends its shoots laden with vermillion-coloured flowers. It is a quite hardy plant, though little seen in English gardens. I saw it last summer in the position mentioned, where it made a very fine effect, but it may be also planted on the rockery, or in a place where its shoots can fall over, or run through neighbouring things, as shrubs. Plant in the spring, and let the soil be rich, giving water also through the spring months until the roots get established. You had better get roots. Plant the remainder, except *Gaillardia* and *Cactus Dahlias*, any time from now until spring, but the sooner they are in the ground the better. I should not risk the *Romneya* in the open unless you are in the extreme south of England, in a peculiarly favourable climate. The *Dahlias* are, of course, better. They are struck from cuttings in the spring, got from old roots put in heat. *Lobelia fulgens* it is also not well to risk in the open. The plants should be divided in *Gaillardia*, unless in a warm soil, are not hardy.—C. T.

ROSES.

A RIVAL TO MARECHAL NIEL ROSE.

THIS is, however, what the new Rose catalogues say, and although many people may be disposed to doubt such an assertion, I am not prepared to say that the catalogues are wrong, as from what I have seen of this new Rose—the name of which is Climbing Perle des Jardins—growing in large and small pots, I am satisfied that, if it does not prove a rival, it will run the *Marechal* very close for the honour of the first place as a yellow climbing variety for cultivating under glass. The name is, of course, familiar to many readers of GARDENING, as the dwarf form has long been known as one of the best Tea-scented Roses in its line of colour. The variety to which I allude is a counterpart of the other, except in growth, which is of a vigorous climbing habit, so vigorous, in fact, that I have seen plants in 9 inch pots that had made shoots 20 feet long during the past summer. In the matter of growth it is undoubtedly a serious rival to *Marechal Niel*, but as I have seen the flowers under a strong summer sun, I do not think the colour is deep enough to displace our old favourite, but there are many people who will value this new Rose for its continuous flowering quality, as even the strongest of the shoots of the current season produces many blooms. This is what the *Marechal* never does. It will flower from old spurs, but not on the long young shoots. Should it be that the colour of the new rival is deeper when forced into flower in the month of March I hardly know what the effort will be on the future position of our old favourite. It will not surprise me if it has to take a back seat, and that very quickly, as the ankering propensity of the *Marechal* is as disappointing that many hitherto disappointed cultivators will hail with delight a variety that is likely to be free from so serious a defect, and that it is serious my own experience again proves this season, for I put out six plants in the month of March under glass, one of which died, three have just kept alive, the remaining two have made shoots about 4 feet long, and the strongest of these has already got a wart forming on the stem, close to the soil. This so-called wart is only another name for canker, which will be sure to end in the death of the plant, so that if I should allow the newcomer to displace the other I cannot be accused of doing so without a sufficient reason. J. C. C.

Pegged-down Roses.—I am surprised that "A. H." (see GARDENING, Oct. 14th, p. 419) should think I am undecided about the

Fig. 2.—Early Turnip "Jersey Navot."

value of pegged-down Roses, as the past volumes of this paper will show that I have advocated this form of Rose growing long before "A. H." had adopted it, and have had nothing but praise to write in its favour. I asked the question of a correspondent as to the behaviour of *Gloire Lyonnaise*, because I had not grown this

particular variety in that way, and, it being a beautiful Rose, I was anxious to know how it behaved. I may mention that I commenced propagating H. P. Roses from cuttings in the year 1868. The next year the plants were set out in beds on Grass, and for twenty years they gave me more pleasure in Rose growing than I have got from any other form. This being so, I can only hope that "A. H." will go on advocating pegged-down Roses, and that he will make many converts, as I am sure they will not be disappointed.—J. C. C.

4776.—Marechal Niel Roses.—It is very desirable that you should thin out at once some of the weakest shoots. Those left would then get better ripened, and produce larger flowers than they will if left as they are unless you so wish it. It seems a pity to allow the Roses to occupy the whole of the roof. In my own practice I cut all the shoots down as soon as the first lot of flowers are over, and then get a crop of Tomatoes in the same house, cutting away the growth of the latter as the young Rose-shoots require the space. Even if you continue on the same lines, you certainly allow too many shoots to remain. You should cut away some of the oldest and weakest and train out these left to 9 inches apart. Mr. Look, an amateur gardener of Staplegrove, near Taunton, grew last year the finest Niel Roses I ever saw. He trained the shoots a long way apart on the back wall end near to the top of his greenhouse, where the growth got all the sun and plenty of air; the blooms were extraordinary, both for their remarkable size and substance. I never saw better evidence of the value of securing well ripened wood of this Rose.—J. C. C.

I can quite understand your reluctance to cut away the wood of two such grand plants as you evidently possess. Still, a great deal of comparatively useless wood may be removed, and there could be no better time than the present. I would remove all of the side growths of indifferent strength first, afterwards cutting away the oldest wood that could be removed without sacrificing more than possible of the ripened growth made during the past summer. You will obtain more blooms from a smaller quantity of good wood than from a lot of medium growth. The strong shoot still growing freely may be left intact. Next spring, after flowering is over, again trim out as much of the wood as possible, thus allowing more space and light for a few strong maiden shoots to develop themselves.—P. U.

4777.—Management of H. P. Roses—There is no great objection to moving your old Rose if you do so at once; but I am afraid the sickly-looking ones will be found not to have many roots. If they have not you had better discard them. About the third week in March cut back all the strong long shoots to within 18 inches of the ground, and the weak ones to half that distance; but for such a border as yours I should suggest that you have all Roses in the back row, and nothing between them. If the heap of stuff to which you allude is free from live roots of weeds, it will do admirably to mix with the old soil, and I should advise you to take out a trench 18 inches deep, and put 6 inches or more of the material in the bottom, and set the Roses on the top of it. Then mix some manure with another portion, and fill up the trench with that and half of the old soil. You want something with an upright growth between the Carnations. Striped Margolds are popular flowers just now. Double or single Zinnias would do very well, but I should prefer the singularly formed and quaint-colored flowers of the Salpiglossia. These will flower quite late in the summer, after the Carnations are over.—J. C. C.

It will not interfere very much with the blooming of your Roses if lifted and transplanted at once. Being on the spot, you can avoid the least delay in placing them into their new quarters, and this is a great point. Of course, it will somewhat reduce the quality and quantity of bloom, and your plants will naturally have somewhat coarse roots after being in one place so long. You are right in allowing them more room, for at present your border must be rather cramped. The decayed weeds and horse-manne you speak of will be quite as good to plant into as anything so difficult to obtain without much expense. The chief thing is to plant early and

without any delay in the operation. What would look best between the Roses and Carnations is purely a matter of personal taste; but I would advise less crowding.—P. U.

4758.—Growing Roses.—"Inquirer" has got a splendid aspect and position for his new venture, and I wish him every success. As a start I would choose the following twelve dark H. P.'s: General Jacqueminet, A. K. Williams, Charles Lefebvre, Countess of Oxford, Earl of Dufferin, Empereur de Maroc, Duke of Connaught, Jean Souperet, Victor Hugo, Prince de Rohan, Marquis Bernardin, and Prince Arthur. When he asks for light-colored Roses I am tempted to recommend all Teas being planted, except Gabrielle Luizet and Mrs. John Laing among the H. P. Perpetuals, and Viscountess Folkestone, Augustine Guinoisseau, Caroline Testet, and Captain Christy from among the Hybrid Teas. The quantity of good, light-colored Teas are so numerous that I must refrain from naming them. Why not write to

Clove-scented Pink.

some grower for a descriptive catalogue? Tea Roses grow remarkably well in Ireland.—P. U.

The best growers amongst the sweet smelling Roses are to be found in those bearing light or rose-colored flowers. You will, however, find the following twelve fairly good: A. K. Williams, E. Y. Teas, Prince Camille de Rohan, Annie Weed, Emily Laxton, Empress of India, Holair, Raoul Guillard, Jean Souperet, Madame Hoair Perreire, Souvenir de Charles Montalet, and Paul Verdier. Amongst the light-colored Roses bearing fragrant flowers I regard Madame Gabrielle Luizet as the best; Augustine Guinoisseau (or White La France) is also very good; others possessing various degrees of sweetness may be found in Caroline d'Auden, Marchioness of Lorce, Duchesse of Albany, Mr. J. Brownlew, Mrs. J. Laing, Marie L. Peznet, La France, Francois Courting, Marie Verdier, and Felix Gray. If you are interested in sweet scented flowers, you may grow the old Cabbage Rose, the Casha varieties and Reine Blanche.—J. C. C.

"Inquirer" should succeed well with Roses in such a position. The best twelve dark-colored Hybrid Perpetuals are Abel Carriere, A. K. Williams, Charles Lefebvre, Countess Pignaneu, Loies Van Hoette, Reynolds Hele, Ulrich Brunner, Xavier Olibo, Horace Vernet, Sultan of Zanzibar, Paul Neyron, General Jacqueminet, Duke of Wellington, and Depey Jamain. Amongst the white or light-colored kinds may be mentioned the following: Augustine Guinoisseau, sometimes classed as a Hybrid Tea, but in reality a H. P. The flowers are white, tinted with pink in the centre, very fragrant, are borne profusely. They are borne with great freedom on sturdy plants both in the summer and autumn. It is also called the White La France; Margaret Dickson, one of the new varieties shown by Messrs. Dickson, of Newtownards, at the Crystal Palace, this year, would suit you, and they are light-colored Roses, although a trifle expensive at present. They are very suitable for Ireland, and it would not be a bad plan to write to this firm for advice in the matter, as Roses that succeed here are not always satisfactory across the Channel. Mr. John Laing is a light-colored Rose, and has done well this year. It is good everywhere. Then there are Abel Grand, Alphonse Souperet, Beroness Rothschild, Boule de Neige (white), the new Caroline Testout, (rose, very fragrant), Centifolia rosea, La France, Mme. Eugénie Verdier, Mme. Victor Verdier, Marquise de Castellane, and Violette Bouyer.—C. T.

4731.—Light-colored Tea Roses, &c.—I think the following are twelve of the sweetest-scented Hybrid Perpetuals of the above colour: Abel Grand, Francois Michelon, Heinrich Seheltheis, Jules Margottin, Mme. C. Joigneaux, Marchioness of Lorne, Marguerite de St. Amand, Baronne Prevost, Miss Hassard, Princess Mary of Cambridge, Silver Queen, and Violette Bouyer. A similar number of Teas may be found in Adam, Devonensis, The Bride, Souvenir de S. A. Prince, Elio Eugier, Goubalt, Edith Gifford, Mme. Cusin, Sappho, Rubens, Sonv. d'un Ami, and Innocente Pirela.—P. U.

PINKS AND CARNATIONS.

THESE plants suffer if left too long in one place without transplanting, for they get long, straggling stems, which suffer greatly in severe weather, while short, stocky plants pass safely through the most trying ordeal. Pink's root so freely when divided and replanted at this time of year, that except for very choice sorts it is the easiest and best plan. The old larger white and pink varieties and the larger-blooming varieties that are now so extensively grown for supplying cut flowers may be increased to any extent by this means, diggling out small trenches and planting them right up to the leaves; every piece will make a plant. Carnations that have been layered will now be rooted sufficiently to be taken off from the old stools, and after the beds are prepared, planting them firmly in lines where they are to flower. Old plants that can be divided will be greatly benefited by digging up and replanting in the same manner as Pinks. I have many times, when dividing and replanting at this time of year, had quantities of shoots broken off without any roots. These have been made into cuttings, and inserted in sandy soil under cloches or hand-glasses, or even in boxes of soil, placing them in cold frames, and a very large percentage of them have rooted by the spring and made good plants; in fact, it is advisable to have a reserve supply of this sort, for in severe winters they seem to suffer less than those that are fully rooted, and in vigorous growth. The illustration represents a good specimen of the favourite Clove-scented Pink.—J. G., Gosport.

The Autumn Crocus.—This is a very beautiful hardy herb, and yet very little grown in gardens, although it is not fastidious. It is more worth growing than many of the Dutch Crocuses that one gets really tired of in the spring months. Crocus speciosus—such is the botanical name of the Autumn Crocus—has deep-purple flowers, a lovely colour, the veins still deeper in shade, and set off by a brilliant orange stigma, which is very rich contrast; when the flowers are fully expanded in the sun they are of a brilliant purple. The bulbs increase readily, and thrive in moderately light soil.—C.

FRUIT.

4728.—**Compost for Vines.**—The best compost for Vines is the top 4 inches of an old pasture with a limestone base. If the limestone base is not there add one or two portions in bulk of old plaster. To this should be added some manurial stimulant of which there are plenty of artificials in the market. Thomson's Manure has an established reputation. The Patent Silicate Manure is excellent for Vines and Peaches, and crushed bones or bone-meal are excellent for mixing into Vine borders. I think the simpler the compost the better. Good loam and bones—one part in twenty of bones to loam—with annual applications of stimulating artificial will grow good Grapes. But Grapes are annually falling in price, and the cheaper they can be produced the more profit—however, the time is near when there will be no profit at all on Grape-growing, unless they are produced cheaper.—E. H.

—The best compost for Vines is turf cut from a pasture, the older the better, as it will have all the more fibre, and it is the fibre that renders the turf valuable. Failing this material, the best soil that can be had must be used, mixing with it suitable additions in greater proportions than would be necessary were turf obtained. To every cartload of turf freshly cut, 3 inches thick, and chopped into pieces 4 inches and 6 inches square, add one sixth part of lime-rubbish, wood-ashes, broken bricks, and charcoal, limiting the quantity of the first and last in proportion to the kind of loam to be used. For instance, if this be of a heavy, close, retentive nature more of the ingredients named will be required to maintain the porosity of the soil; but where the loam is inclined to be of a sandy nature less of them will be needed. To each load of the mixture, whether it be heavy or light, add $\frac{1}{2}$ cwt. of $\frac{1}{2}$ -inch ground bones. These ingredients may be added in making up the border, which is preferable to mixing the whole together previously, because by constant turnings over of the compost to as thoroughly incorporate as is thought necessary, the loam or soil becomes broken up so finely as to lose much of its porous nature when put together, and consequently is more liable to become inert and too close to admit of a rapid discharge of the water, which of necessity must be applied copiously from time to time for the support of the immense quantity of foliage which healthy Vines carry. It is a mistake to add farmyard manure to the soil. This only induces the Vines to make grass growth devoid of maturity. Under no consideration should the border be made too deep. Shanking of the Grapes is more often traceable to the roots being in soil too cold than anything else. A depth of 2 feet of soil is ample for any Vine border. Drainage should be provided amply. One foot of broken bricks, stencos, or clinkers is not too much to carry off surplus water quickly. In making a new border it is not wise to complete it at once; rather make it piecemeal by adding a couple of feet in width every year until the limit is reached. The Vines will thus obtain more support by their roots being able to run into new soil.—S. P.

4771.—**Grapee for a cold-house.**—I should not advise anyone to plant Alicante Grape in a cool-house, for at best it is only third-rate in flavour. The fact that Alicante will thrive and the berries take on a good colour if grown on the back wall of a vinery or greenhouse makes it a favourite with some amateurs; but if I had to eat the fruit I am sure I should strike for a change. For a cool-house Trentham Black is more suitable than Alicante; but why not grow Black Hamburg or Foster's Seedling (white)? You will never get better sorts. If you do not want large bunches and berries the Dutch Sweet-water is far and away superior to Alicante in flavour.—J. C. C.

—The Grape that the most confidence can be placed in to ripen in a cool-house is Black Hamburg; none equals this old favourite. Independent of its adaptability for a cool structure, the quality of its fruit cannot be surpassed. Alicante is a bumpy Grape, but in point of individual quality it is sadly lacking as compared with Black Hamburg. Trentham Black is not good for a cool-house; it fails to get well sometimes even in a heated structure.—E. H.

4752.—**Blight on Apple trees.**—I expect the soap-water was not strong enough. Sulphur is not of much use to kill these insects. Linseed-oil smeared over them will kill them, so will paraffin; but I have seen trees injured by the use of paraffin, and do not recommend it, except it can be mixed with soap and afterwards tined down with water. A strong solution of Sunlight Soap, 6 ounces to the gallon, will kill all kinds of aphids. This will, I think, prove a cheap and useful insecticide.—E. H.

—“Pomona's” trees are infested with “American Blight,” commonly known as the woolly aphid, a most difficult pest to get rid of. If the trees are not too badly overrun with the insect as to cause excrescences all over the branches, pare many of the worst parts down to the level of the bark of the branch, and well scrub every part of the tree with methylated spirits, using a hard brush. If the washing is carefully done twice during the winter the bulk of it will have been got rid of. Even if that is so, some is sure to show during the summer. These should be touched with more of the spirit, and with persistence the trees may be rendered tolerably clean.—S. P.

—Your trees appear to be affected with the “American Blight.” Petroleum or paraffin-oil is a certain remedy for the pest. I have cleared a great many trees with it these last few years. Last spring I used it about some trees that were very badly affected. It completely freed the trees from the pest for the season. It will probably appear again next spring when the trees must have another touch up with the oil. I apply the remedy with a small paint-brush, and use it undiluted with water. It needs no rubbing in as petroleum-oil has strong penetrative powers. I have never seen any ill effects from its use.—L. C. K.

4738.—**Cape Gooseberry.**—For pot culture it is best to treat this plant as an annual, and then it is of very easy culture. Sow the seed in March, and afterwards grow on in single pots. Those 7 inches in diameter will furnish quite a large plant. I have a plant at the present time in a 6 inch pot that is furnished with lots of fruit, but which has had only ordinary soil and plenty of water. If planted out in good soil early in the summer it will cover quite a large space in two or three months, and insects do not trouble it. The flowers are insignificant, but the fruit is of an ornamental character.—J. C. C.

—This is a native of South America and is closely allied to the Potato and Tomato, and will do very well under the same cultural conditions as the latter. I have fruited the plants out-of-doors in the summer planted against a south wall; and they will do still better if they receive the same treatment given to Tomatoes under glass. May be raised from seeds or propagated by cuttings, the latter being I think preferable, when good cuttings can be had. If planted out under glass in a span-roofed house they will commence bearing early and continue all the summer. They are accommodating in the matter of temperature; they will bear a warm-house, or if kept on the side of dryness at the roots they will pass through the winter in a greenhouse where the frost is kept out. I once grew a lot in a cool orchard-house, but a severe frost killed nearly all the plants. If the most is done with them they should not have a lower temperature than 50 degs. to 55 degs. at night. They will grow in any good soil. The plants bear on the young wood and a supply of this should be encouraged.—E. H.

4754.—**Young Vines.**—Many young Vines are ruined by leaving too much length of rod the first year, and many persons aim at covering the trellis too quickly; the result is after a few years of indifferent crops of fruit the rods require renewing. Well-managed Vines ought to last thirty years in good condition, and give as good bunches from the lowest spurs as from the opposite end of the Vine. A greater length of rod should not be allowed to remain at the first pruning than will provide one pair of side shoots and a leader; which means that the cane should be cut back within three buds of the first wire.—S. P.

—If you value the future more than the present, leave about 4 feet of wood to fruit above the bottom wire, and take about 8 bunches of Grapes. Such Vines will fruit a longer rod, and many growers nowadays would make them do it.—E. H.

4773.—**Apples, &c., for a small garden.**—Instead of having two trees of Eohlinville, why not have one of Lord Suffield or Lord Grosvenor, and one tree of Irish Peach, which ripens its fruit in August, instead of two of Cox's Orange Pippin, good Apple though it may be? The season would be made much longer, and more variety would be enjoyed. Governor Wood is a better Cherry than White Heart, ripens earlier, and the fruit is of superior quality. In the place of one Victoria Plum why not plant a tree of Jefferson? This is a prodigious bearer, while the quality leaves nothing to be desired.—S. P.

4763.—**Grapee not colouring.**—Over-cropping the Vines is a common cause of the non-colouring of the berries of this Grape. During that stage the hot-water pipes should be kept warm to maintain a buoyant atmosphere both night and day. The ventilators at the top of the house should always be open a little way to enable impure air to escape and admit fresh, causing a free circulation, opening the ventilators a little at the front on favourable occasions also. If the night temperature does not fall below 50 degs. the Grapes will colour all the faster. Examine the borders to make sure that the roots do not suffer for want of water. If the soil is too dry the roots cannot feed the Vines to enable the berries to colour properly.—S. P.

4753.—**Planting a Pear-tree.**—Directly the leaves fall is the best time of the whole year to plant fruit-trees of any kind. Fresh roots are then made before the drying winds of March set in; the trees consequently succeed much better the first year than though planting is postponed until the spring. If the soil is heavy and retentive of moisture, it should be trenched 2 feet deep at once, keeping the surface-soil in the same position as it was before. By moving the soil to the depth named surplus water from heavy rains so much more quickly passes away during the autumn and winter months, the wood ripens so much better, and canker is less likely to take place, than where there is a want of maturity of the current year's growth. Do not add manure to the soil, except it is very poor in quality, then a small quantity of half-decayed horse-manure will be an advantage. This, however, ought not to be buried deeply. In the case of heavy soil the tree should be planted on the surface, mounding the soil around it sufficient to cover the roots with 3 inches deep. Choose a dry day for planting, then the soil can be trodden firm about the roots. After planting place a stake alongside of the tree to prevent the wind moving the roots from their position. Mulch the surface for 2 feet around the tree with a 3-inch thickness of partly-decayed manure.—S. P.

—Plant the Pear now—the sooner the better. Break up the soil well, and place some good loam round the roots in planting. Do not plant too deep. Mulch with manure, and stake as soon as the planting is done.—E. H.

4737.—**Scale on Peach-trees.**—Wash the trees as soon as the leaves are down with Gleanst Compound, 4 oz. to the gallon. Give another dressing in February after pruning, and these will be no more trouble with scale.—E. H.

—When the leaves have fallen carefully scrub the infested parts with a strong solution of Tobacco-water and soft-soap, using a fairly hard brush. If the branches are handled carefully and the work intelligently done, no harm need happen to the buds on the trees. A second washing will remove any missed the first time.—S. P.

4774.—**Freake of Nature.**—A graft of Plum has been placed upon the Apple branch, no doubt. It is not a freak, but done purposely. You have evidently pruned your trees to death. If you leave them alone you might get some fruit, but not if you deliberately cut off all the young growth.—C. T.

The St. Bruno's Lily.—The beautiful St. Bernard's Lily and St. Bruno's Lily, named respectively A. liliago and A. liliastrium, are two very attractive garden flowers, and useful to cut from for the house. Everyone who has a garden likes to see flowers from the border in the house. If only one kind can be grown, choice should be made of the St. Bruno's Lily, which in a light yet deep soil throws up its spikes of pure-white flowers like miniature Lilies. The best times to plant are the autumn or spring, and beware of small marauders in the shape of slugs that seem to find the tender leafage delicate fare. The flowers of the Anthericum are so pure-white and graceful that they may be used in the choicest arrangements. I seldom see it in small gardens, but I have had it very beautiful this year in quite a small place.—T.

TREES & SHRUBS

CLEMATIS DAVIDIANA.

This useful Clematis is not cultivated as much as it deserves to be. Its large, deep-green, Vine-like leaves and clusters of pale-blue flowers, of a very rare and delicate quality of colour, entitle it to a place in the choicest collections. Probably it is only hardy in our southern counties, and even there likes a warm sheltered place and a little dry Fern for winter protection; but its distinct character and refined beauty will repay a little care and trouble. It forms a bushy plant about 2 ft. high and flowers in July. B.

4768.—Creepers on West end houses.

—The creeper which looks like a Virginian Creeper on many of the houses about Grosvenor-place is a Virginian Creeper, but not the close-clinging kind. Its proper name is Ampelopsis hederacea. It is a fast grower and very ornamental, but its non-clinging tendency is rather against it for those who want a creeper that requires no training. There is a variety of this called muralis, which does cling closely, and I think is the best Virginian Creeper I ever saw, combining the close-clinging character of A. Veitchii with the free, graceful leafage of A. hederacea. It should be well and widely known. Some plants that I had planted in April of this year are now quite 12 feet high, and they have not been watered nor had the slightest attention since planting. They cling to the wall most tenaciously.—A. H.

— I presume the creeper you mean is the Veitch's Virginian Creeper (Ampelopsis Veitchii), which clings close to the wall, and is much used in London gardens. It is a free-growing and most useful climber, and does not need nails to support the growth, while the leafage turns to brilliant colours in the autumn.—C. T.

4736.—Striking evergreens.—The best time to put in cuttings of evergreens is during September and October, if planted in the open ground; but Conifers and such things as are rooted under glass should be put in earlier. Cuttings in a dry time must be well watered, and where only a few plants are required it will save trouble if the cuttings are planted in a shady position on the north side of a wall or fence.—E. H.

— It is considerably too late in the season for this to be successful. September is quite late enough. Such evergreens as Laurels, Sweet Bay, Laurustinus, Privet, Eonymus, Aucubas, Griselinias, &c., would root freely on a sheltered border, if put in during the early part of September. During the present week I have been engaged in putting in some evergreen cuttings of choice varieties; but these are kept close and under glass. In the open it is really too late, the wood being rather too matured to callus freely.—P. U.

— Many kinds of evergreens will root readily from cuttings, but very few in the open ground. Laurels, Box, Aucubas, and Ivies of sorts will grow fairly well, but the choicer kinds need the protection and assistance of a cold frame for at least nine months. No time should be lost in inserting the cuttings out of doors of those kinds previously named. Choose cuttings about 9 inches long of the current year's growth, retaining with each a piece of the old wood, commonly called a heel, as from this roots are more readily formed than from the softer part of the shoot made during the current year. Instead of cutting off the shoots with a knife they should be slipped off by holding the branch in one hand and with the other give the cutting a sharp downward tug. Trim off any loose bark at the heel. Insert the cuttings 4 inches deep in rows 10 inches apart and 4 inches from each other. If the soil is heavy seek for a small quantity of sand at the bottom of the trench, on which the base of the cuttings rest. Roots are more quickly formed in sand than soil. Press the soil firmly about the base of the cuttings, as upon this much of the success or otherwise depends. If the base of the cuttings is loose how can roots form in the soil? On the surface between the rows lay a mulching of decayed leaves, Cooco-nut-fibre refuse, or even coals-ashes an inch thick to prevent the frost up-heaving the soil, and consequently loosening the soil at the base of the cuttings.—S. P.

4765.—A Laurel shrubbery.—The principal cause of the Laurels dying is the constant clipping to which they have been subjected.

Laurels will not stand such treatment unless the roots are kept nourished by an annual top-dressing of soil or manure, especially when they are growing under trees. You had better root out the old plants and take away a good quantity of the old soil, and after putting fresh earth in its place put in some more Laurel-plants, and instead of clipping them with shears, use a knife to cut away unruly branches. It is not likely, however, that the plants will trouble you with too much growth. Nor must you expect them to remain in a vigorous condition unless you help the roots in the direction I have indicated.—J. C. C.

HOUSE & WINDOW GARDENING.

4707.—Campanulas in pots.—These plants will do better in a window than in a frame during the winter, as they are apt to mildew, and slugs, too, are so fond of them that it is difficult to save them from being eaten up unless indoors. They are excellent window plants, and will do well in any room without severe frost, being given all the sunshine and mild air available. The proper time to divide them is in the autumn, and cuttings put in during the spring do not often flower at once. Campanulas, however, do not often need re-potting; the beautiful plants hung up in cottage windows, covered with a mass of bloom in summer, are often left in the same pot year

Clematis Davidiana. Engraved from a photograph.

alter year, and still go on blooming. It is best to let them become quite pot-bound before they are interfered with, when they can be divided in August, just after flowering, and they will then make handsome plants again the next season. Cuttings are much longer in attaining the needful size and strong, hardened growth on which the blossoms are so abundantly borne.—L. L. R.

4766.—"Geraniums" in winter.—These plants should be potted up at once and placed in a window for the winter, if possible in a room where there is a constant fire, but they will do in a spare bedroom or bathroom with a sunny aspect, if special measures are taken to keep them safe during a frosty time. They should have been cut back rather sharply in September, so as to relieve them of some of their tops, if at all large and old, but young plants do not require much pruning, and are better without it unless it be done early enough for the wounds made to thoroughly heal and harden out of doors, as they are apt to become mildewed and kill the plant if they are made at the time of potting up. Take them up with as much of the soil adhering to them as practicable, and place them in pots which will just hold them comfortably (and no more), filling in the sides with sandy soil and leaf-mould—no manure. Make the plants very firm in the pots, with good drainage, covering the crocks with a little Moss, sprinkled with soot; and if the weather be mild and not too wet, let the plants stand on a bed of ash or of

slates or glass, for a few weeks to harden thoroughly before taking them indoors. They must, however, be sheltered before sharp frost sets in, but will do well under a verandah or any sort of protection in a sunny spot for some weeks, unless we have an early winter. "Geraniums" are nearly hardy—in fact, they live outside year after year in South Devon, so that all they require is to be kept safe from severe frost when in pots. But mildew is more likely to kill them than frost indoors, and this enemy must be guarded against by gathering every falling leaf as it lodes and burning it, never allowing any sort of rubbish or rotting stems to be about the plants, as mildew seeds itself rapidly, and will destroy a whole set of plants, if allowed to do so. The remedies are dryness, especially of the air, and a slight sprinkling with flowers of sulphur on the infected parts. "Geraniums" should be kept as dry as possible during the winter, only being watered occasionally, when enough must be given to run through the pot, so as to water all the roots thoroughly, the saucers, if used, being emptied half-an-hour afterwards, as they must "never" stand in stagnant water, except when in full flower. A kitchen window is an excellent place for "Geraniums" in winter, and they may be wintered in a dry frost-proof cellar, if kept out of doors as much as possible to harden, and brought up as early in the spring as practicable, sheltering them again in the same place during a sharp time of frost. Or they can be put into a corner of a room away from the glass during frost, and covered with several layers of newspaper which will protect them enough if they are dry at the roots. After the cold is over place them out of doors in mild rain, which will do them much good, taking them in at night in case of frost recurring. In the window of any sitting-room with a daily fire they will do very well, especially if a newspaper be put between them and the glass in slight frost, and they are moved into a sheltered corner, as above, when the weather is very severe. In March they may receive a shift into a pot one size larger, with good rich soil; they will be covered with buds and ready to put out again early in May.—L. R.

— In answer to "F. F. Richmond" as to keeping "Geraniums" in winter, I kept mine successfully last winter in a cellar, the pots resting on old boxes. The window opened toward the south, and it was opened for an hour or two on all dry, sunny days, unless it was actually freezing, watering very seldom, and taking all decayed leaves off. About the end of February or beginning of March I bought some potting-soil from a nurseryman, and taking every plant from the pots, I scrubbed the pots both inside and out, and repotted the plants in the new soil, taking shippings vary liberally. I kept them in the same cellar for another week or so, giving air freely, and then moved them into a tiny lean-to greenhouse without any artificial heat. I was truly ashamed of them, and the nurseryman laughed at them, but the result has been most satisfactory—far beyond my expectation. I have had nice, healthy, fine plants, and very fine bloom both in the tiny house and the few I had to bed out. I should think if you have a sunny room where you burn a lamp instead of gas it would take the place of my tiny house, but such plants must have fresh air, but avoid a draught.—C. R. F.

— You may keep the plants in a window or spare room, and I have hung mine up by the roots in a cool cellar, and they have lived well through the winter. In the early spring they are taken down, cut back, potted in light well-drained soil, and they start away well. Then you can get cuttings from them, if you have a little heat to start them. The great thing is not to give much water when the plants are in pots—indeed, scarcely any—and remove decaying leaves. Damp kills wholesale, and the cellar in which the plants are hung up must be cool, and, of course, away from the influence of frost.—C. T.

— This is rather late in the day for potting up "Geraniums," unless there is artificial heat available. They may be kept in the windows of a room where fires are occasionally burnt, giving only just enough water to keep the

INDOOR PLANTS.

4749.—**Treatment of Gloxinias.**—I should recommend you to leave them as they are until the spring. When the foliage drops away, do not continue to water, but let them dry off; stand the pots on a shelf out of the way. About March or April, the new growth will begin to break; then take up and repot in a mixture of about two parts good fibrous loam to one each of leaf-mould, peat, and silver sand; water them in and keep moist and warm; there is no difficulty about growing and flowering; but they should be watered with a spout below the foliage, not overhead; water dropping on either flowers or leaves rapidly decays them.—A. G. BUTLER.

—Better leave the Gloxinia halves in the pots till the growth begins in spring; then shake out and repot in loam, peat, and leaf-mould, about equal parts, rendered porous by using sharp sand freely. These plants used to be grown chiefly in peat and sand years ago, but it is now found that greater development can be obtained from a stronger, richer soil.—E. H.

—The best compost for these charming plants is a mixture of loam, peat, leaf-mould, and sand, about two parts of the first to one each of peat and leaf-mould, and half a part of sharp or coarse sand. Drain the pots well, and pot firmly. The halves should be started in a gentle hot-bed in the spring, using small pots and light, sandy soil; shift them on as they grow, and keep them moderately warm and shaded, with a humid and rather close atmosphere, at any rate during the early stages. Water freely, and give a little weak liquid manure as the flower buds rise. When the bloom is over, dry the plants off gradually and store away in a rather warm and dry place for the winter.—B. C. R.

4743.—**Mignonette, &c.**—To have Mignonette to flower in the winter the seeds should be sown not later than August in the best loam which can be obtained, and made quite firm before sowing. My plants, which are in bloom now, were sown in July. Another batch was sown in August, but these plants are not showing flowers yet, as they have been kept in a cold pit, freely ventilated, the flowers not being required before Christmas.—E. H.

4728.—**Ornamental leaved plants.**—This is a very difficult question to reply to satisfactorily, partly because fashions change, and new plants are introduced from time to time, which take the lead for a time, at any rate. I remember when the very handsome large-leaved plant, *Cyanophyllum mesgiferum*, was first introduced it was for a time found in every first-prize collection. *Sanchezia nobilis variegata* when first introduced was run upon for some time; but neither of these plants are much seen now. The truth is, exhibitors who make a business of showing grow plants which can bear carting about the country without injury, and wisely go in for such things as Palms, Cycads, Crotons, *Draenas*, *Anthuriums*, *Pandanus Veitchii*, or something that will make a good specimen, and that can bear exposure. It is of no use to grow a delicate thing that exposure injures or perhaps kills. Again, a good deal depends upon the skill brought to bear. Foliage-plants for the most part are not difficult to grow, but it requires some degree of cultural skill to bring them out in the best possible condition. If I was picking out three foliage-plants for carting about to show I should select something that would stand wear and tear, and grow them into es fine specimens as possible, trusting that size and freshness of condition would carry the necessary weight to win—a good Palm or Cycad, a good Croton, and a good *Pandanus Veitchii*. *Phryma* will, I think, make a very useful exhibition foliage-plant. It is a very distinct thing, and is not difficult to grow. *Anthurium crystallinum* well done is a striking thing. *Alocasia metallica* well grown is also useful. Some of the *Marantas* are pretty, but most are too small of stature for this work. But it is necessary to do foliage-plants well that there should be a good well-heated stove.—E. H.

4766.—**Building a small greenhouse.**—Do you intend to make the house with a span-roof or a lean-to? This makes some difference. A suitable height for a span-house of the size

named would be 7 feet to the ridge-plank, with a roof-pitch of about 25 degs., which would give the height to the eaves something less than 5 feet. The side beds or stages (and the walls also) might then be 3 feet in height, leaving 2 feet on each side for glass. If to be constructed without side-lights, take the side walls up a foot higher than the beds, or say about 3½ feet, and make the roof so much steeper, laying the wall-plates directly on these, and the rafters springing from them straight to the ridge-plank. The plates may be of 5-inch by 3-inch stuff, the end rafters 3 inches by 2 inches, and the rest (rebated for the glass, of course) 3 inches by 1½ inches. The ridge should be 7 inches by 1½ inches, and the door posts 3 inches by 3 inches. The roof ventilators, two on each side, may be 2½ feet by 1½ feet each, hinged to the ridge-plank.—B. C. R.

4724.—**Best Fuchsias.**—You may select any of the following. It is a little difficult to name only one, but I give the names of a few to each section. Of the dark coloured kinds select *Abundance*, the sepals of a bright reddish colour, the corolla deep purple; *President*, the tube vermilion, corolla violet, a variety of excellent habit; *Try-me-O*, a splendid kind, fine in colour, robust, and free; *Lye's Rival*, tube red, sepals purple-violet. The following three are good: *Lye's Excelior*, tube and sepals rose-magenta, corolla of a carmine tone; *White Souvenir de Chiswick*; and *England's Glory*, a very good exhibition Fuchsia.—O. T.

4751.—**Coronilla and Oytisus.**—Do not repot the plants now; the right time to do this is in the early summer, when the flowers are over, and before the fresh growth begins. After the treatment they have had they ought, with the aid of some weak liquid manure, to bloom profusely next spring, and should then be pruned, re-potted, and grown on again.—B. C. R.

—Judging from my own experience of these things, I should say—Don't. If well nourished many plants will put up with small pots, but in the case of hard-wooded things this is often overdue. I should recommend a shift into pots a size larger, running in all round them a compost of loam and well-rotted manure.—A. G. BUTLER.

4730.—**Greenhouse plants.**—A well-grown *Plumbago capensis* always useful in August, and it is an easy matter to have a specimen fresh in bloom in August. Among the triolors, *Hatfield major* will be in good condition then.—E. H.

4610.—**Keeping Fuchsias through winter.**—The Fuchsias will keep in the cellar with *Begonias* and *Dahlias*; but it would be as well not to cut them down until it is time to start them into growth early in the spring. The soil should be very dry, for if it is moist and the cellar rather on the warm side they would start to grow, which would be disastrous.—J. D. E.

4697.—**Plants for a cold greenhouse.**—You cannot grow very many things in a greenhouse not heated in the winter, but in the summer you could have several plants. I should rely largely for the late autumn and winter upon *Chrysanthemums*, which thrive readily in such a place, if carefully cultivated, and you will find in recent numbers of *GARDENING* much information upon this flower. Of course halves may be grown, but you would do well to heat the structure with a small oil-stove or similar appliances, then you can have such things as *Zonal Pelargoniums*, *Fuchsias*, and plants of that character. Try good *Ferus*—forms of *Lady Fenus* end others.—C. T.

4642.—**Flowers for Christmasehurch decoration.**—The best white flowers for Christmas decoration are *Arums* (*Calla aethiopica*), which can be brought on in pots, with very gentle heat, to flower at Christmas, if procured at once; but the plants must be strong and well grown, having spent the summer in a rich border in the open air and been potted up in rich compost during September. *Arum Lilies* are very hungry and thirsty plants, needing plenty of luke-warm water, while forcing, with cancers, and rich top-dressing when the soil is lowered an inch or 2 inches by their strong and rapid growth. The plants should now be in a cool greenhouse, heat being only put on when the temperature goes below 45 degs. To open at Christmas the heat must be increased to 55 degs., with a higher temperature on sunny days. Paper-white *Narcissus* and Double *Rosa* *Narcissus* may possibly bloom in time if potted at once, but it is now late for them. *Roman Hyacinths*, however, are still available, as they grow very quickly. All the above-named bulbs bear slight forcing, without which they would not now be in time. *Narcissus Tazetta*, which flowers in seven or eight weeks from the time of potting, can be had in time.—LUNNERS

RULES FOR CORRESPONDENTS.

Questions.—Queries and answers are inserted in *GARDENING* free of charge if correspondents follow the rules here laid down for their guidance. All communications for insertion should be clearly and concisely written on one side of the paper only, and addressed to the Editor of *GARDENING*, 37 Southampton-street, Covent-garden, London. Letters on business should be sent to the Postoffice. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Unanswered queries should be repeated. Correspondents should bear in mind that, as *GARDENING* has to be sent to press some time in advance of date, they cannot always be replied to in the issue immediately following the receipt of their communication.

Answers (which, with the exception of such as cannot well be classified, will be found in their different departments) should always bear the number and title placed against the query replied to, and our readers will greatly oblige us by advising, as far as their knowledge and observations permit, the correspondents who seek assistance. Conditions, soils, and means vary so infinitely that several answers to the same question may often be very useful, and those who reply would do well to mention the locality in which their experience is gained. Correspondents who refer to articles inserted in *GARDENING* should mention the number in which they appeared.

4757.—**Growing Larch from seed.**—When cones are collected, how is seed separated and prepared for planting?—L. A.

4738.—**Pears on a clay soil.**—Will some kindly tell me whether staff loam would grow Pears fit for market purposes?—READER.

4750.—**Herbaceous plants and rabbits.**—I shall be glad if a list of herbaceous plants least likely to be destroyed by rabbits?—R. V. O. B.

4730.—**Lobelia erinus.**—Information asked as to the best way of preserving a good strain of *Lobelia erinus* through the winter?—LUCAN, Dublin.

4791.—**Plant for a vinery and greenhouse.**—Will someone kindly inform me what are suitable inexpensive plants for keeping in above?—F. N.

4792.—**Fruit-trees for a north-east wall.**—I shall be glad if anyone will give a list of Pears, Plums, and Cherries most likely to succeed on a wall with east aspect?—R. V. O. B.

4793.—**A leaky roof.**—Is there any way of doing up the roof of a large glass-house, and prevent drip, except taking off the glass and reputtying it, so that is such an expense?—D.

4791.—**Myrica Crista-galli.**—I saw this plant in good form at Kew a few weeks since, and shall be glad to have particulars as to cultivation, and also to know where it can be obtained?—T. A. F.

4795.—**Superphosphate and Potatoes.**—Will anyone kindly tell me if there is any danger of superphosphate causing Potatoes to rot? Not having used any myself, I should like to make sure before I tried any.—D. Z.

4796.—**Green Tomatoes.**—I have a lot of green Tomatoes on the stems. What is the best thing to do to ripen them? They appear to be still growing in the cold greenhouse, but I want the room for other things.—NORMAN.

4797.—**Black Currants.**—My Black Currant bushes have set such large buds on their new growth this year, they are as large as Peas, and appear just on the point of bursting. Shall I have fruit next year?—A. BORTONLEY, Deunbury.

4798.—**Seed Potatoes.**—Would someone kindly give me the particulars regarding the steeping of Seed Potatoes in a solution of sulphate of ammoniac and nitrate of potash, given in the *Standard* some time last year?—A. SUBSCRIBER.

4799.—**Best kinds of Rhubarb.**—Will someone kindly tell me which are the best kinds of Rhubarb? I should like some for forcing—some early outdoors, and a main crop. Also state the best time to procure roots for planting?—VINEX.

4803.—**Fenon behind a border.**—I propose potting a fence about 6 feet high, with the back of a herbaceous border, on which to grow *Roses*, *Clematis*, &c. Would wire rabbit netting attached to wooden posts be suitable for the purpose?—E. C. M.

4801.—**Celery.**—This year my Celery (red and white) looks most healthy, and of very full size, but when dug, cleaned, and cut the heart is soft, brown, and a pulpy rotten mass. I cannot discover any cause. What would be the probable reason?—L. F. B.

4802.—**Clematis flammula.**—Will "J. C. O." or someone else kindly tell me why this *Clematis*, planted 8½ years ago, and full of bloom during the past two months, has not the sweet scent that it usually has? It is growing over an old Plum-tree.—T. G.

4803.—**Climbing Roses.**—Will someone kindly give me the names of half-dozen good hardy climbing *Roses* suitable for a wall facing north-west, and half-dozen for a wall facing south-east? Also a dozen good hardy bush *Roses* suitable for middle beds between these two walls?—URLANDS.

4874.—**Seedling Anemones.**—I have a lot of seedling St. Bilgid's Anemones, some showing bloom-buds. They are in a span-roof cold frame. Which is proper treatment? 1. Take them up and store away? 2. Take up and transplant into bed? 3. Take up in spring and transplant?—W. B.

4806.—**An unheated greenhouse.**—I have an unheated span-roofed house, divided by lathes-work down the centre. On this I have *Roses* (*M. Niel* and *Niphetos*); they have now covered the lathes and reached the roof. I find the height of the house will only allow them to be trained about 3 inches from the glass. Will the frost damage the plants when so close to the roof? Can I grow *Roses* in pots on the stages underneath?—S. H. F. B.

4806.—*Convolvulus minor*.—Are these good bloomers, or did I get the better plant, *Tropaeolum*? This summer I planted Dwarf *Nasturtium*, but they did not bloom, yet the tall kinds bloomed splendidly in the same soil. Please give the names of a few *Tropaeolums*, because I think they will stand snooks well?—H.

4807.—Using manure.—I have been collecting a good quantity of horse and cow-manure. Shall I lay it on the ground now seed level for the winter, or leave it to rot during the winter, and dig it in in the spring? My ground is pretty full of perennial. Any advice would be gratefully received.—ENQUIRER.

4808.—Treatment of a Fig tree.—I have a Brown Turkey Fig-tree planted against a wall facing due south. It makes abundance of foliage and wood, but the fruit, when reaching maturity, turn yellow and all fall off. Will someone who understands give an suggestion as to cause, and how to remedy same?—HARRIS.

4809.—*Roya carnea*.—What time of the year is the best to procure this, and what sort of plant lets, and what colour are the blooms, and at what season do they bloom? Any information as to treatment, its habit, &c., will be thankfully received by me, as I thought of buying some if they can be grown in a window facing south-west.—H.

4810.—Planting Briars.—I am just going to put in some Briars. Should they be planted rather deep, and should the shoots on which they are budded next year be allowed to grow wild until the following spring? If not, when should they be cut back, and how long ought they to be before moving Briars after budding, please?—NOMLAE.

4811.—Hardy Fuchsias.—What kinds would be hardy in Middlesex, planted outside under a wall 10 feet high, facing south-east? It is well sheltered from east, north-east, and north winds, and they could be covered up with straw in winter. If any sorts would do, when would be the best time to plant? It is a snaky district.—H.

4812.—A garden at Leyton.—I have just moved here, quite close to the Leyton Station, G.E.R. Would some gentlemen kindly give me an idea of what the soil is about here? Is there any chance of growing a Rose? The soil seems poor, but fear I must try. Should like an idea of what does best in ordinary garden perennials (no greenhouse)? Have trod out my Lilies, &c., to sink or swim.—A. A. M.

4813.—Growing for market.—I would like to know what would be most profitable to grow for the market in a cool house, 60 degs. at night, 20 feet length, 12 feet width, and 9 feet height? Tomatoes and Cucumbers have done well during the summer, but the heat is not strong enough for a succession in them. Would French Beans do for one thing? Shall be glad of any suggestion.—IN DUBFAIR.

4814.—Treatment of Vines.—I have a vineyard with four old Vines in it, but they have been neglected, and this year I only had 9 bunches of Grapes on them, and that was an one Vine. I had animal's blood put on the roots, but it does not seem to have done much good. Will anyone else kindly inform me what is the best measure in use, when they ought to be pruned, and where I could find a competent man to do the pruning? I would be glad if other information will be thankfully received.—VINNER.

4815.—Basilic flag.—Will anyone kindly give me some information about flag ("Basilic flag," I think it is called) as a dressing for Grass-land, or for kitchen or flower garden? I heard of it some time since, and was told that it was very good and much cheaper than ordinary artificial manures; and I afterwards heard that it suited some lands only, and was very prejudicial to others. I should like to know what descriptive of soil or plants it is suitable for, how it should be applied, and where it can be obtained?—C. W. C.

4816.—Fixing hot-water pipes.—I should be glad if someone could kindly give me instructions for fixing my hot-water pipes. My system has been laid on a great pressure in the pipes, and they leaked so badly I could not use the apparatus. The pipes are closer together at the far end than at the boiler end, owing to the bend being short; supply cistern is fixed to the return pipe, near the boiler; also how much rise should the pipes have? Would a 2-inch pipe between boiler (which was made for 2 in.) and the 3-inch pipe used, hinder the circulation? I cannot get the 3-inch pipes tight on the 3-inch boiler neck.—G. B. I.

4817.—A hot-water boiler.—Will "B. C. R." kindly advise me in the following: Having purchased a hot-water boiler (Star pattern), with an arch-way out of one end, 9 inches wide and 4 inches deep, length of boiler 30 inches, and 17 inches external width, I should be glad to know the most efficient way of setting same in boiler-work? Also what quantity of piping it is capable of working steadily? I may say that I am out quite a novice, having constructed a coil furnace after "B. C. R.'s" instructions, which has worked perfectly. The chief part of my present difficulty is the plan of the flues, and whether to use the said arch for the furnace door or for flue.—J. W.

4818.—Ferns for a heated conservatory.—Will someone kindly tell me what Ferns and Mosses will suit a conservatory, moderately heated by hot-water pipes in the daytime up to 60 degs. or even 65 degs.? It is on the south side of the house. Three sides are glass, with windows above and at the sides to open, size 20 feet by 7 feet. I live in Baywater, London, and wish to grow some large hardy Ferns high up, and some smaller and fairly delicate Ferns low down among the tufts and osmunda, which forms a rocky overhanging pool. I want to hide the rock-work well; there is plenty of osmunda. Will *Smilax* trail up the wall in this conservatory, or does it require more moisture? Perhaps "C." who gave an illustration of "a rock pool fernery," in GARDENING, October 21st, can advise me!—PASH.

To the following queries brief editorial replies are given; but readers are invited to give further answers should they be able to offer additional advice on the various subjects.

4819.—*Camphora officinarum* (Siamensis). This is the name of the plant you send, the Chinese

Camphor-plant, and distinct from the Bornean and Sumatra *Camphora*, which is the produce of quite a different plant, called *Dryobalanops camphora*.—J. J.

4820.—*Dianella speciosa* (Benj. Mann).—The berries you enclose appear to belong to this family. They are very pretty and showy. The plants are for the most part natives of Australia and New Zealand, and they will thrive well potted in well-drained pots in some what stiff, loamy soil. Sow the seeds in autumn.—J. J.

4821.—*Cyrtopodium Harrisianum* (J. Austin).—The flowers seem to resemble this, the first garden hybrid *Cyrtopodium* raised by my poor friend Dooly at the Messrs. Vetch's nursery, Chelsea. But it is a very poor form of the plant, which I advise you to destroy. Some very fine forms of it have been raised, but I cannot name yours amongst them. I would certainly consign it to oblivion.—M. B.

4822.—*Cyrtopodium Schroederi*.—J. Austin sends me four flowers of this variety, and asks what I think of them? All I can say is that *Cyrtopodium*. It was introduced some few years ago by M. Linden, of Brussels, and though it approaches Linden's old *lobata* closely, I do think that there is sufficient distinctness to warrant the name given by M. Linden; but it appears to me that the old original form *lobata* by Lindley was an exceptionally good variety, and perhaps it is a good thing that at the present time there are not many that know the genuine old form named by Lindley, which does allow many of the old forms to retain to merit the name of superb, but which in comparison are only in a second place.—M. B.

4823.—*Cattleya labiata Waroocooana*.—J. B. sends me four flowers of this variety, and asks what I think of them? All I can say is that *Cattleya*. It was introduced some few years ago by M. Linden, of Brussels, and though it approaches Linden's old *lobata* closely, I do think that there is sufficient distinctness to warrant the name given by M. Linden; but it appears to me that the old original form *lobata* by Lindley was an exceptionally good variety, and perhaps it is a good thing that at the present time there are not many that know the genuine old form named by Lindley, which does allow many of the old forms to retain to merit the name of superb, but which in comparison are only in a second place.—M. B.

4824.—*Pleione lagnaria* (T. T.).—The flowers of this plant are exceedingly beautiful, but to me they appear duller than usual, as, say, in the latter end of next month (November); they are very beautiful, however, whenever seen. The best plan is to stop with this and the other species which flower very freely is to pot them up in rather broad, shallow pans, with an empty small pot in the centre, and then in the autumn, when the *Pleiones* have lost their own leaves, and the flower buds begin to appear, a Fern which has been grown for the purpose should be inserted in the centre of the pans, to compete with the *Pleiones*. Thus foliage could be added to them during the time of flowering. All the kinds go by the name of Indian Crocus when in flower.—M. B.

4825.—Hardy Ferns for a cool-house.—G. Moore, in writing to me about these things, is loud in his complaints about a certain dealer, who he says has quite taken him in. The A. Filix-femina and its varieties were very handsome and pleased him well during the summer; but he had asked for evergreens, and, not knowing Ferns, he kept them, when sent, with *Aspidreas* and others, so going off. What he is to do, the best thing to do is to go to some respectable dealer, who will perhaps charge you a little more and treat you honestly. You will need to go in for some forms of the evergreen Shield Ferns (*Polytaichium*), some Hart's-tongue and varieties (*Asplenium nidus*), *Polytaichium*, *Lomaria splendens*, *Asplenium Trichomanes*, and A. *Adiantum-nigrum*. With these you should have a few foreign kinds, such as *Oryzium acrostichum*, *C. falcatum*, *C. Fortunei*, *Diloyogremma japonica*, *Oxybium japonicum*, and such like plants. You have done like a great many others and find and ask advice afterwards. If you do not receive these you would not have been in the middle you are; but when you get some evergreen species do not cut your *Filix-femina* on one side; they will come up in the spring and be beautiful again.—J. J.

4826.—Names of plants and fruits. *Any communications respecting plants or fruits sent to name should always accompany the parcel, which should be addressed to the Editor of GARDENING ILLUSTRATED, 37, Southampton-street, Strand, London, W.C.

Names of plants.—G. T. Moore, 1, *Cyrtopodium venustum*; 2, *Odonoglossum Schlieperianum*; 3, *Odonoglossum Cervantesii*; 4, *Oncidium myrtilloides*.—N. B. Moorhill, 1, *Catantopium luridum* apparently; *Epipedium hookerianum*; *Dendrobium draconis*, not Low; this has a yellow flower, with a red-crested lip.—M. Hatch, 1, *Yavalla alpina*; 2, *Rhipidopteria petata*; 3, *Oleandra Wallichii*.

POULTRY & RABBITS.

4827.—Keeping Pigeons.—As I am thinking of keeping Pigeons, and not having had any previous experience with them, would someone kindly answer me a few questions? I wish to keep them solely for table purpose; therefore, would like them to be good breeders, and also good-sliced birds, as I would kill them while young. Which breed would answer the purpose best? Also what would be the best food to give them in order to fatten them off quickly? To what ages would they breed probably? I should have to restrict the other sex with a batch of young ones as one would fowl? Also how often should they be fed—only as often as fowls are fed, or often, and how many times could I expect in a year from each pair? As time is rather an object with me, an early answer to the above will greatly oblige.—BUA ROCK.

4828.—Keeping cock, etc.—I should feel grateful if "Doulton" will advise me about my poultry. I have a very fine cock—cross between Game and Houdan. He is two and a half years old. Could I keep him with good results a year longer in the yard, or would it be best to get rid of him? I have had a young cock given me—cross between Plymouth Rock and Houdan. Is this considered a good stock? I should like to know if "Doulton" will advise me. I have been successful with my poultry. With the old birds and 609 pullets from January 1 to September 1, I had 1,000 and 699 eggs. They are kept in pairs, but well cared for.—IVY BANK.

4453.—Fowls ailing.—I always associate the rattling in the throat, to which "Ivy Bank" refers, with the commencement of a cold, from which the fowl may recover in due course, provided the weather be favourable, but which may also develop into something far worse, and at last result in the death of the bird. From the fact that the querist's hens have laid freely for some months, I conclude there is not much the matter with them; but, at the same time, it is right to point out that laying hens are not at strong at the end of the season as they are earlier in the year, so that they cannot endure such severe attacks of disease. All that "Ivy Bank" need do is to take care that the hens are not subjected to severe draughts whilst on the perch and about the throats of the effected birds by dosing them twice daily with a teaspoonful of glycerine or linseed jelly.—DOULTON.

BIRDS.

4593.—Cramp in a bird's legs.—Immerse the legs in warm water, about as hot as you can comfortably bear your hand in, for about twenty minutes, then dry with a warm flannel and afterwards hang up the cage in a warm place free from all draughts. If this does not cure it float two or three drops of olive-oil on the drinking water, as it will then be evident that it is caused by indigestion. For small birds this, in my opinion, is the only safe purgative.—A. O. BUTLER.

4492.—Food for Doves.—Dori and White Millet are the only e they require to keep them in health. I never knew them to eat any kind of green food.—A. O. BUTLER.

BEES.

4493.—Management of Bees.—Will any Bee-keeper kindly give me advice about my Bees? Last year I had a swarm, and to this I added in the autumn two stooks of Bees, making my hive very strong, and had great hopes of having a good supply of honey this summer, but have had none, and the Bees seem to dwindle away, so I asked a man who understands Bees to have a look at them, and found the queen covered over with what he calls parasites. I can find no such disease in any Bee book. He destroyed this queen and procured me a new one, and also added another stook, and sprinkled Keating's powder over them. He assured me this would effectually destroy any remaining parasites, but I am not at all satisfied with such meagre information, and would like to know the cause, and how to prevent a recurrence? I am a beginner, so may be supposed, and I stupidly bought a hive made by a local man, which it is impossible to see into. Seeing the mistake I made in my purchase, I have bought a new one from a neighbour; but still for the present I urate on the old hive as well. I shall feel grateful if anyone can help me? I may add that when we uncwared the hive the bees were very strong, and the hive full of honey and brood.—IVY BANK.

BECKENHAM, KENT.—To be sold privately, a DETACHED BIJOU RESIDENCE, suitable for a modest family; situated in a high ground, overlooking on one side an extensive park, situate with the old timber and no the other commanding fine views in the direction of Forest-hill and Sydenham. The grounds, of about 15 acres, are well laid out and planted with choice trees and shrubs. The house is large, with the kitchen garden productive and well stocked with fruit-trees. The house is substantially built, the reception-rooms lofty and well proportioned, with convenient domestic offices on ground floor. There are on bedroom floor seven bedrooms, dressing-room, bathroom, &c. Good stabling for three horses, coach-houses, poultry-house (with run), gardener's tool-shed, &c., &c. The property is held for a term of about 70 years, at a nominal ground rent of 24 lbs. per annum.—Particulars from A. M., care Editor, 37, Southampton-street, W.C.

EXPIRATION OF LEASE.—E. TANNER begs to inform the public that he can offer his fine apoclim and general nursery stock at half price. A grand lot of plants suitable for planting out, unsightly buildings. Also a large stock of ever Christmas-trees. Marvellous value.—E. TANNER, Broadwater Nursery, Groombridge, Sussex.

£400 BUYS the old-established and well-connected BUSINESS of BEKESMAN, FLOREST, and FRUTERER. Good shop and house. Best position. Six acres land well stocked. Greenhouse, &c. All in good going order. Instruction given to beginner. Rare chance. Healthy locality. Thirty minutes by rail from Birmingham.—F. FLOREST, 12, St. George's-square, Worcester.

WANTED at once an energetic and thoroughly qualified man to take entire charge of a Farm and Orchard of 120 acres in Oxfordshire. The Orchard was planted about 20 years ago, and contains about 1,200 selected trees, together with the usual small fruit. There are 11 Glass-houses, two with Vines in full bearing, nine for Tomatoes and early flowers and vegetables. There is large vegetable garden. The land is, or will be, in Grass. There is a capital house on the farm, well furnished, and good out-houses for poultry and dairy work. A small salary will be paid to a competent man, who will be required to take entire management of the concern, and will receive a portion of all profits made. Apply by letter, addressed to OXBERT-FIELD, East Cliff Gardens, Bournemouth, stating experience and what salary required.

SITUATION WANTED as Head Working Gardener of good Single-handed where help is given; good experience in herbaceous plants, Roses, Carnations; age 40; married; no family; good character.—U. BUDD, Moolands, West Hooley, Sussex.

A. VIAN

JONES & ATTWOOD

IRONFOUNDERS, STOURBRIDGE.

HEATING APPARATUS

Supplied with various arrangements of Pipes for Greenhouses, &c. Catalogue from Jones' Treatise, "Heating by Hot-water," 120 Pages, 50 engravings. Cloth, 2s.

STOVES

TERRA-COTTA—PORTABLE—FOR COAL.
Greenhouses heated 24 HOURS for about ONE PENNY without attention. ROBERTS' IMPROVED PATENT PORTABLE TERRA-COTTA STOVES for COAL give pure and ample heat with common coal, or coal and coke. For GREENHOUSES & BEDROOMS, &c. Pamphlets, drawings, and other illustrated Testimonials sent. See in our Patentees' T. ROBERTS, 34, Victoria-st., Westminster.

HEATING APPARATUS,

From £4 4s. and upwards.

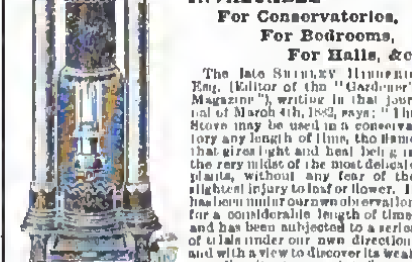

Full Particulars and Local Agent's Address from
R. JENKINS & CO., ROTHERHAM.

THE AUTOMATIC DAMPER.
ECONOMY OF FUEL & LABOUR.
REGULARITY OF TEMPERATURE.
R.H. SOCIETY'S SILVER MEDAL.
Numerous Testimonials.
97, FLEET STREET, E.C.

FOUR-BUSHEL Sack of best LEAF MOULD (pure Oak-leaf) 3s. 6d. Three bushel sack of prepared Potting Compost, 3s. 9d., carriage by Road (London) for Cash.
K. VAN DER MEERSCH Queen's Nurseries, Sellin, S.E.

THE "SYPHON" (Clark's Patent)

HYGIENIC GAS-HEATING STOVE.
NO FLUE REQUIRED.
NO SMOKE OR SMELL.
NO DIRT OR TRUBBLE.
NO DANGER.
INVALUABLE

For Conservatories, For Bedrooms, For Halls, &c.
The Late **SHIRLEY HERRICK**, Esq., (Editor of the "Gardener's Magazine"), writing in that journal of March 4th, 1882, says: "The Siphon may be used in a conservatory any length of time, the flame that gives light and heat being in the very midst of the most delicate plants, without any fear of the slightest injury to leaf or flower. It has been in my own observation for a considerable length of time, and has been subjected to a series of trials under our own direction, and with a view to discover its weak as well as its strong points."

Of all IRONMONGERS, STOVES, & GAS COMPANIES, Or of the Patentees—
S. CLARK & CO., Siphon Works,
181, KINGTON, LONDON, N.

THE STOURBRIDGE HEATING APPARATUS.
Consisting of Independent, Blow Combustion Boiler with damper, 18 ft. of 4-inch pipe, supply chimney, 6 ft. of smokepipe and joints complete for 63ins. Price, delivered free to any railway station in England or Wales £4. Illustrated Price List, free on application—
J. & W. WOOD,
Birmingham St. Foundry, STOURBRIDGE.

THE CONICAL BOILER
is the Cheapest, most Efficient, and Economical boiler ever invented. For heating Greenhouses, Conservatories, Warehouses, Churches, Chapels, and for Amateur Gardeners. Requires very little attention. Will burn any kind of fuel, and cannot burn hollow.
Sole Makers:
NEWSUM, WOOD, & DYSON,
BEESTON ROAD, LEEDS.
Prices and Testimonials on application.

FIR-TREE OIL

SOLUBLE INSECTICIDE.
The most pleasant and reliable of all insecticides for destroying insects on plants, animals, and birds. Thousands of testimonials received from all parts of the world. Bottles, in 6d., 2s. 6d., 4s. 6d., 7s. 6d., 12s. 6d.; in bulk, 11s. per gallon, with full directions for use.
Wholesale from all Horticultural Dealers.
E. GRIFFITHS HUGHES, Victoria Street, MANCHESTER.
NEW YORK—ROKER & SONS.

LET TO OUR READERS.—In ordering goods from these pages, or in making inquiries, readers will confer a favour by stating that the advertisement was seen in **GARDENING ILLUSTRATED.** Our desire is to publish the largest amount of trustworthy business, and the name of the sender of each order should be written legibly.

ROSES.

GRAFTING ROSES.

In their seasons I have already touched upon two methods of propagating Roses—viz, from cuttings and by budding upon suitable stocks. I now propose to write a few notes upon a third method—grafting. At first this may seem a little out of season; but as the stocks should be prepared now I thought it better to treat upon the subject early enough to cover the whole operation and culture, until the young plants may safely undergo ordinary treatment.

STOCKS.—These are many and varied. Briers, both seedling and cutting, should be lifted now and potted into a rather light compost of leaf-soil, loam, and sand. Manetti-stocks also need the same treatment. In potting these do not use a larger pot than will comfortably cover the major portion of their roots; nor is deep potting advisable. I use a 2½-inch to 3-inch pot, and am satisfied if three parts of the roots come into contact with the potting compost. Like the operation of budding, it is advisable to get the graft as close to the crown of the stock as possible, and for the same reason—viz, the avoidance of suckers from the stock. This is more easily accomplished when the crown of the stock is well above the soil; and, as we shall be pinning the stock directly it is potted, and also after grafting, there is no object in covering the whole of their roots with the first potting compost. When potted, plunge them in a pit or cold frame, only covering and shading them just sufficiently to keep them from shrivelling. In about six weeks you will find they have commenced to form new roots, and are now ready for grafting. Stocks can be purchased from almost any nurseryman. Both there is even a cheaper way of starting than this. Where a Rose has died, and the Brier-stock has lived on, the latter may be lifted and portions of its roots utilised as stocks. Choose pieces with a fair amount of fibre, and put them up in the same manner as stocks. This will also suggest a means of increasing your own stocks where their roots are sufficiently strong to allow of a few pieces being removed, or one can graft on a few roots from the hedgerow. In this letter form the Manetti-root is not so suitable as the Brier. Before passing on to the operation of grafting I may point out that it is not absolutely necessary to pot up the stocks previous to grafting the Rose upon them; but as we do not want the young roots to be broken and disturbed during the operation of grafting, and also because it is better for the stock to be a little in advance of the scion, it is preferable to pot them for a few weeks first.

THE SCION.—This may be in two distinct stages of growth, and I will treat briefly upon each in turn, first of all taking the ripe or dormant scion. Both of the scions are much better if they can be procured from plants growing under glass, the wood being more solid, and entirely free from the effects of frost. A ripe scion may consist of one or more eyes. I prefer to have at least two; but one must be guided in

this matter by the amount of suitable wood available. If possible, choose wood of the past season's growth, neither too strong nor weak. Where more than one eye is upon the graft endeavour to have one as near to the bottom as possible, because this will almost always make a stronger shoot than the upper eye. It does not much matter whether the graft be from a long rod of growth, or consist of the shoulders of shorter and lateral wood. We now come to what is styled a "green" graft. This is procured from wood about half ripened, and generally carrying healthy and fully-developed foliage. This will be farther alluded to under the heading of

GRAFTING.—We will suppose that our stocks are ready, and the time suitable; say from December to February. Shake away the loose material the stock was plunged in, and hold the pet firmly between the knees. Now cut off the top of the stock about two to three inches above the crown. Let the cut be in a slightly slanting direction, and on the longest side of the stock commence to pare away a little of the bark and wood. Before going farther I will give the reason for choosing the longest side of the stock. If we selected the lower side of the slanting cut for operations any superfluous moisture that might reach them in the propagating-case would run down into the severed portions of scion and stock, thus causing, or, at any rate, encouraging, damping and rotteness where it is not wanted. By choosing the other side we can sprinkle the grafted stocks without fear of this. The amount of wood to be pared away from the stock depends entirely upon the thickness of your scion. I do not approve of too much being removed; the real aim should be to fit the bark of both sides of the graft to the corresponding bark of the stock. Cut the scion in a slanting direction, letting it be of the same length as that upon the stock, and as nearly as possible at the same angle. In fact, they should fit to one another more or less throughout their whole length. One very important detail is to see that the bottom end of the scion is well down upon the lower portion of the cut upon your stock. This is one of the earliest and most important points of union. Some operators make a slight downward cut in the stock and an upward one in the scion, thus forming a small tongue upon the latter, and fitting this into the cut made in the stock; the object of this being to hold them in place during the process of tying. A few growers claim that it has a material influence over the union, but as my own experience has proved it to be quite immaterial, I never waste time over it, believing it best to make as few cuts as possible, either upon scion or stock, seeing that all have to be healed over. Having tied the scion firmly to the stock we now place it into a close propagating-case. Where such a useful adjunct to a greenhouse does not exist it may be met by using a box or boxes sufficient to hold the number of Roses you wish to graft. Half plunge the boxes upon a warm border or bench, and plunge the grafted stock up to the portion where the scion joins. If you can arrange to cover the boxes with glass, and shade them so much the better, if not,

simply cover with a mat or sack, and so keep them partially close and dark at the same time. Do not keep them too wet. A temperature of 60 degs. will be best for the first six weeks, and as they commence to grow remove the forwardest to another box, affording them a little more light and air until they are gradually inured to full light and the usual temperature of your house. Any dormant eyes that may have been upon the stocks are almost sure to put in an appearance while they are in the bottom-heat and under cover. Needless to say, these should be removed at once, and as closely to the stock as possible. As soon as the union is complete, and the graft well on the move, shift your young plants on into larger pots, if possible bringing the soil half-way up to the union of scion and stock. When shifted again, they may be placed a little deeper still. This encourages the Rose to produce suckers, and also strike off upon its own roots, thus materially assisting in its support. Do not afford too large a shift at first; two or three pottings should intervene between the 2½-inch and an 8-inch pot. Of course, a little stronger and richer compost will be advisable at each successive potting up to this stage. The method of operating upon a "green" scion is slightly different from the above. In the first place, the stock needs to be more forward in growth; sufficiently so, in fact, to allow of the bark being lilled. For this reason early spring is the best time for the operation; and, fortunately, it is then that we are able to find the best wood for the purpose. Keep the stocks more backward than in the case of autumn grafting, bringing them into heat about a month previous to grafting, so that the sap may be rising to meet the requirements of the young wood we are going to use. Commence by cutting off the stock as recommended for the first style; but instead of paring away any of one side, make a close cut with the point of your knife, from the crown to the top of the stock. Now prepare the scion by cutting it much the same shape as before, but letting the lower end be a great deal thinner. Lift the bark of the stock gently, and slip the point of your scion underneath, pushing it down to the bottom of the cut. Bind the whole together, and treat similar to the ripen graft.

4810 — Planting Briers.—When first planted in the hedgerow these are best placed some 6 inches or 9 inches in the soil. Previous to this they should be trimmed. Remove almost the whole of the old and coarse roots, as those will decay after a few years. Also trim off all of the Brier-stem which may be above a crooked shoulder or knot. The Brier is no use above these, and there is no object in leaving the stem too long. Some growers trim off the shoots in the autumn after being budded, but my practice is to wait until spring. The year after being budded they will produce a good head of Rose growth, and may be lifted and transferred to any desired quarters the same autumn. At the second planting it is well not to plant quite so deep as I have recommended for the unbudded

1803.—Climbing Roses.—The six hardiest climbers I can recommend you for the north-west wall are: Gloire de Dijon, Cheahunt Hybrid, L'Idéal, Mme. Alfred Carrière, Mme. Bernard, and Kaizerin Friederich. Six suitable for a south-east wall: Reine M. Henriette, Bouquet d'Or, Belle Lyonnaise, Climbing Perle des Jardins, Emilie Dupuy, and William Allen Richardson. A dozen good hardy bush Teas, giving a variety of colour, would be: Homère, Marie Van Houtte, Souvenir de S. A. Prince, Mme. Lambert, Dr. Grill, Trompée de Pernet Père, Ernest Metz, Anna Ollivier, Sunset, Mme. Faloot, Mme. des Tartes, and Catherine Mermot. Six good Hybrid Teas for your purpose would be found in: Grace Darling, Caroline Testont, Anguotine Guinisseau, Viscountess Folkestone, Camene, and Gnetave Regia.—P. U.

—North-west is not a good aspect for the better forms of Roses, but such as Gloire de Dijon, Mme. Planter, and Sir Joseph Paxton will thrive, only they may be later in coming into bloom. To these you may add Aimée Vibert, Magna Charta, H.P., and Climbing Victor Verdier; the last-mentioned is dark red in colour and delightfully fragrant. For the south-east aspect my selection would be W. A. Richardson, La Marque, Cheahunt Hybrid, Réve d'Or, Reine Marie Henriette, and L'Idéal. Twelve good hardy Teas will be found in Mme. Lambert, Marie Van Houtte, Mme. Faloot, Mme. Engène Verdier, Countess of Folkestone, Grace Darling, The Bride, Anna Ollivier, Perle des Jardins, Comtesse de Nadailac, Princess of Wales, and Catherine Mermot.—J. C. C.

GARDEN WORK.

Conservatory.

During damp weather a little fire will be necessary, even in mild weather, to dispel damp. The modern Chrysanthemum, with the large blooms, will not bear a close atmosphere, which at this season will always be more or less damp. When damp settles upon one of these large blooms it is speedily spoiled. Dead foliage must be removed very frequently, and cleanliness everywhere is most important. If hard-wooded plants are kept in the conservatory, arrange them at the cool end of the house. Heaths in bloom will require careful watering. A daily look over should be given, though the plants may not require water every day. If mildew makes its appearance dress with black sulphur immediately. Insects of all sorts must be promptly dealt with either by dipping or fumigation. I prefer dipping in an insecticide bath where only a few plants are infested, but when a house has been given over to insects for some time, fumigation must be resorted to. A well-ventilated, well-arranged conservatory, with its varied odours of flowers, and leafage, and brilliant blossoms will be a cheering sight now; but to keep all things moving on in a satisfactory manner requires knowledge and care. For the most part the potting for this season is over, but this is a good time to lay in a stock of potting soils. Good loam is necessary to the plant grower, but it is sometimes difficult to get. Old manure reduced almost to humus is difficult to mix with loam for many plants. Good peat and clean sand is required for hard-wooded plants and Orchids. These different matters should be laid up in readiness now. When other materials are not so pressing, the gardener, if he does all that is required of him, has no leisure. It will soon be time to begin taking cuttings of Chrysanthemums for next year. I sometimes think, in the case of most kinds, the early cuttings do not always produce the best flowers. I have to-day been looking at two plants of Chrysanthemum Ayalachino. One was struck second week in December, and the other nearly a month later. There is no difference in the flowers, and the thought arises, why strike so early? Where now has a limited number of plants it may be desirable to begin taking cuttings early, but it is very important that none but strong, vigorous cuttings are taken. I would rather wait a time for cuttings, if I could get stronger stuff by doing so. Cinerarias in small pots must have liquid manure, and 5-inch pots would be considered small for Cinerarias.

Stove.

Bulbous and tuberous-rooted plants will, for the most part, now be going to rest. Such things as Gloxinias, Calceolarias, and Abohmias should be laid up their sides where they will not get damp. I have kept all these under the stage in a coolish greenhouse. The rest is more perfect, and early in the spring they can be returned to the stove again, and they will break all the better for the rest. Early sown Orchids, including Calceolarias, will be coming on now. I maintain a steady temperature of 65 degs at night will be quite high enough for general collections of stove plants, and where a temperature of 70 degs. is kept up, that last 5 degs. of heat costs a good deal at the present price of fuel to keep it going. Cuttings of India-rubbers, Crotons, and other foliage plants will strike now in bottom-bush, and it is as well, where more stock is required, to strike these things now to relieve the work of the propagator in the spring. Lose no opportunity of dealing heavy blows at mealy-bug and other insects.

Forcing house.

Forced flowers will be in request now for cutting, and the Lily of the Valley, if the crowns are well ripened, and

the true Berlin variety may be started now; but unless the crowns are good, it is of no use starting them. It is not every grower of Lily crowns that supply the best crowns. One may send in an order and get quite an inferior sample. They may appear plump, but not being well matured, they will not bear forcing. The only chance one has is to deal with a first-class grower. I have a number of pots of Lillies which were forced last year, and they are now well established with well-ripened crowns. These are on first batch, and will not disappoint, as I know from previous experience. Spireas should all be potted, but there is not much gained by piling in heat too early, as the more roots they are given the stronger they will start. This is true of all forcing. There is a right and a wrong time for the beginning of forcing any subject, and, to a great extent, that time is influenced by the preparation given to the material and previous years. It may be said anyone can buy plants prepared for forcing, but all will not turn out alike, even when so prepared; so much depends upon the proper ripening of the buds.

Ferns under Glass.

There is a strong reserve of decorative force in a large house full of Palms and Ferns. The True Ferns are grand things for furnishing, so also are a few of the best Palms, such as the Kentia and Scaevola, but, unfortunately, now requires a large house to keep them in. No one recommends potting either Palms or Ferns at this season. Still, if a plant is pinched up in a small pot, I should not hesitate about shifting it on. Where there is a genial temperature, and the wickler of the water-pot is an old hand, it matters little when the potting is done. Ferns must always be kept moist at the roots. If permitted to get dry, the fronds die, and the plants fail to begin afresh, and make new growth. Cytosium falconum is one of the hardiest Ferns and is largely grown for market. I don't think it matters much when Fern spores are sown. If there is a genial temperature sown now in a shady part of the house, where the atmosphere is confined.

Window Gardening.

Bulbs which were started early will now be making growth, and should be carefully looked to the light, sufficient water being taken to keep all the soil moist. Freesias are growing fast, and will require support, and should occupy a light position. Hyacinths, Tulips, Narcissus, including the Chinese Sacred Lily, are coming on. This Lily, as it is termed, will grow just as well in earth as in water. I grew a number last year potted like other Narcissus bulbs, and they flowered very well. Foliage plants, India-rubbers, Palms, Aspidistras, Aralias, and Dracaenas will derive much benefit from a weekly sponging with soap and water.

Outdoor Garden.

At the time of writing (October 22nd) Dahlias are fuller of blossoms than they have been all the season, and the foliage has never been brighter or fresher. Very pretty and useful are the Pompon variety, both in the garden and also in a pot; but the frost that disfigures tender things must be near, and then the roots must be lifted, dried, and stored away in a cool place, as my Dahlias, Tuberos Begonias, and Genas in cool-houses, packed close on the border, where the frost is only just kept out. I don't think it is quite the right thing to peek totem away in close, stuffy places where the damp will injure them. If Gladioli have not been lifted they should be taken up now, the top cut off close to the bulb, and the latter placed in a dry room to complete the ripening. If water is poured through the Gladioli grounds of a large garden, and exhibited for a few days, and he is lifting some of his choice seedlings to avoid being any of the small spaw or bulbets, which form round the base of the bulbs. Everybody who grows Gladioli should save seeds and raise seedlings. In good, suitable soil they are better sown to the open in drills in the same way that the small spaw are sown which are taken from the present season's bulbs. Even the most successful growers have the disappointment of seeing bulbs die, but where the practice of raising seedlings is followed, and the plants are regularly carried out there will always be something new and interesting coming on. The weather is now very suitable for planting operations. Both evergreen and deciduous things will move safely now. Torf also may be laid.

Fruit Garden.

Hardy fruit culture is annually assuming larger proportions. There is, in spite of the low price realised this season, a future before Apples and Gooseberries. Even in this season of plenty those who have storing room will not do so badly with the Blenheim and other good-keeping sorts. It will grow. Free-bearing trees will require manure this season, but it should not be raked or fresh, especially if laid near the roots. In planting fruits, or, indeed, anything else, the manure should never be placed in actual contact with the roots. Have it near where they can reach it when they require assistance. Spiced weather does not potting or planting of dwarf fruit-bearing trees. Fruit may also begin now, as the leaves will soon be down on Pear-trees, though the absence of frost this autumn has kept the leaves longer on the trees. Many Pear-trees are too much crowded with wood, and should be thinned. I have seen good results follow the removal of some of the old branches, so as to give more space to those left. Making two leaves grow where there is only space for one is not good culture. The outcry against pruning has pretty well found its level. Common sense generally comes to the front in time. And the non-pruner and the pruner who goes to extremes with the knife will find their occupation gone. New plantations of Raspberries may be made now. Those who cling to the old plantations will lose the benefit to be obtained from planting the new and improved kinds, such as Superlative, Hornet, and Norwich Wonder. Deep trenching and liberal manure is a necessary preparation for Raspberries.

Vegetable Garden.

Box and other edgings may be replanted now. I am not much in favour of Box for vegetable gardens. It requires care to keep it in good condition, and it forms a famous hiding place for slugs and other insects. Blue clove are much nearer ad better, and not much more expensive. There will be accumulation of vegetable refuse in all directions now, and everything should be utilised as manure. Where trenching is being done weeds and other matters which decay quickly may be trampled in and

easily got rid of. Where much pruning has to be done the outtings may be used to start a fire in the rubbish-yard, and as soon as the outtings are fairly kindled commence with the drier of the waste materials, and follow this up by adding heavier, greener rubbish until a large smoking heap has been got together, that will be a valuable fertilizer in the spring for top-dressing Celery beds, Carrots, and other crops, as soon as the leaves have died down on Beakale and Rhubarb preparations may be made for forcing, either by lifting the roots and planting thickly to a new position where heat can be applied, or the crowns may be covered with pots, and surrounded with a mixture of leaves and manure in sufficient bulk to raise a temperature of 60 degs or so. One of the best French Beans for forcing is the Ne Plus Ultra. These may be planted in quantity now in 5-inch or 7-inch pots, and placed in warm-houses near the glass. It is best in planting Beans to work half all the pots with soil, the other space to be filled up when the Beans are up. Five Rows in each pot are quite enough. E. HODDY.

Work in the Town Garden.

Frost will keep off, and, refreshed by the recent heavy but not unduly cold rains, gardens everywhere, both in town and country, are looking brighter and better now than at any other period of the year. With me the Michaelmas Daisies are not quite so fine as usual, owing, no doubt, to the long and most trying drought; and "Geraniums" and other tender bedders are, of course, getting the by now, but the Tuberos Begonias are quite a feature—fuller of bloom, larger, brighter, and altogether better than ever. Those invaluable plants, the White (and Yellow) Snapdragons, too, are still in full bloom, and afford quantities of flowers for cutting. In heat or cold, wet or dry, the plants have got on remarkably brightly throughout the whole of the season. By the time these lines appear in print most if not all of the leaves will be off the trees, and the garden should consequently receive the usual autumnal cleaning up. It is almost useless to sweep up much, or frequently, until the trees are bare; but a thorough clearance should be made now, the borders be lightly forked over (except where newly planted with bulbs or the like), Grass and edgings out for the last time, and the well-trimmed, wooded, or cleaned in some way, and the walls washed. The bedding plants (Begonias and Dahlias only excepted) should be lifted and housed now, and no time should be lost in finishing the planting of Hyacinths, Tulips, Snowdrops, Crocuses, and other hardy bulbs. Cinerarias also ought to be planted without farther delay, though in very smoky districts it is advisable to keep part of the stock of the choice kinds under glass, and plant out in the early spring. These plants are making wonderful progress now; even where they almost succeeded to the ground they are now growing luxuriantly again, and quite late layers are mostly ready to be transplanted. Remember always to plant these, as well as Pinks, and, indeed, the whole of the Dianthus tribe, as firmly as possible, and to mix some burnt earth, mortar-rubbish, or both, in the soil. Do not cover or mulch the plants or beds in any way during the winter. It is the greatest mistake imaginable. A little fresh coal-ash round each plant is the least mistake, but even that is not to be done. The bedding plants (Chrysanthemums under glass very freely in each weather as this, but use a little warmth in the pipes at night, just to dry up damp and keep the air in gentle motion. On the whole, the plants are looking remarkably well now, and lovers of this popular flower will enjoy many a treat, not only among their own collection, but by visiting the various exhibitions that are now so numerous, not only in and near London, but in most parts of the country also. H. C. R.

THE GOMING WEEK'S WORK.

Extracts from a garden diary from November 4th to November 11th.

Looked over Grapes in late houses to remove berries showing any tendency to decay, but as the house is always kept in good repair very little damp finds entrance into the houses. Inside potting is very important, in late vinerias especially. I generally paint these houses inside every two years, and at this season when moisture is rather high, the glass is not so high, it is either dried down or removed. In many vinerias the Vines are trained too near the glass. Vines should never be trained nearer than 16 inches—18 inches will be better—so that there may be a clear space between the foliage and the glass. Cleaned all foliage from Peach-houses. The wood is quite ripe, and to leave fall on the merest touch. I want the house for Chrysanthemums. Like most of our friends and neighbours, we have caught the Chrysanthemum contagion, and when one is badly hit with this disease there is never room enough to house all the plants. But though an all-round man may rail at so much fuss being made of no case of plants, there is no gaudy thing that Chrysanthemums are the flowers to brighten up the garden in autumn and early winter, and with plenty of late kinds there will be abundance of flowers for cutting till middle of January, or perhaps later, where properly looked after, and with cool-houses to keep them back. Beside the ordinary Chrysanthemum, the main features now are Chrysanthemum, but to addition there are groups of Bourdarias, Chinese Primulas, and Primula obconica. Early Cinerarias are just showing colour, and Roman Hyacinths are ready to move up. A group of the semi-double "Geranium" F. V. Eschalp is very bright. Those small groups are placed on the outskirts of the Chrysanthemums, and are surrounded in some instances, blended with Ferns. A batch of spring-down Tuberos Begonias in 5-inch pots still make a good show, and show to a very marked manner how vastly the Tuberos Begonias have been improved within the last few years. Pruned back the last of the summer-flowering creepers. We woot all too light now. Very bright just now in the wall covered with Ivy-leaved "Geraniums," and the flowers are exceedingly useful for cutting. Finished earthing-up Celery. Two Mignonette sown earlier in August, and kept in a cold pit, freely ventilated, has been planted and opened out, so as not to draw up by crowding. A light position near the glass and plenty of ventilation is the best for Mignonette in winter. The soil in which

In cold or northern districts the operations referred to under "Garden Work" may be done from ten days to a fortnight later than in the districts where the results.

Mignonette is sown should be rammed as firm as possible. This is with us a main point in the culture; and the soil should be chiefly composed of rather heavy loam. Sifted or Peas-sand. The early blooming varieties have been in the flowering pots for some time. Dipped Cinerarias in a solution of Sunlight Soap. This, about 2oz. to the gallon, makes an excellent insecticide, and it is very cheap. It is used for dipping any plants which are of a manageable size. It is much cheaper than fumigating for clearing off aphides, thrips, &c. Moved Autumn Giant Cauliflowers, turning in to a cold pit. Elkherto the frost has done no harm, but we are not safe now. Busy pruning Gooseberries and other fruit-trees and bushes. I like to get this work done as early as possible, as it permits of the ground being mounded and turned up for the winter. Made a new plantation of Raspberries, selecting vigorous canes only. It is a mistake to leave Raspberries too long on the same land, if fine fruits are required.

STATICES, TENDER AND HARDY.

FOR greenhouse and conservatory decoration Staticeae are invaluable, inasmuch as they bloom freely, remain in good condition for a long time, and are so easily cultivated that young plants of them may be grown quickly into fine specimens. Last year's growth made into cuttings early in the season (spring) may be potted singly in thumb-pots in a mixture of leaf-soil and sand, and placed in a close atmosphere in a top and bottom-heat of 65 degs., where they will root in a short time. Young plants may also be obtained by making a notch on the hard stems of old plants about 2 inches below the undermost leaves, and tying a small handful of Moss round the incision, which must be kept constantly moist, in order to induce young roots to be emitted. As soon as these make their appearance the stem should be severed from the parent plant just underneath the Moss, and it should be potted and treated for a short time as if it were a cutting. The propagation of Staticeae is the most difficult part of their culture; but, by following either of the methods just referred to, young plants may be had in abundance. They should, in all cases, be moved out of their cutting-pots before the roots become matted; and at this, and all subsequent shifts, the compost used should consist of loam, leaf-mould, peat, or well-rotted manure, and plenty of sharp silver-sand. They may be shifted on when necessary until a 12-inch or 14-inch pot is employed for them, but it will take a good many years before that size is needed. They never require more than a greenhouse temperature at any time throughout the year; and if not in bloom they may be placed out-of-doors during the hottest summer months. Plants which have bloomed in summer and autumn should be kept somewhat dry at the root during winter, and, when repotted in spring, they may be placed in a gentle heat until fresh growth is somewhat advanced. Staticeae often bloom even in 4-inch pots, and by pinching their time of flowering may be deferred if a succession of bloom be desired. They blossom naturally from July until November; but by pinching they may be had much later even than that. The indoor varieties of them are not very numerous, and among them the best is *S. profusa*; it is not so robust as some of the others, but it forms a compact and beautiful plant, very suitable either for purposes of exhibition or for decoration, and it blooms abundantly in winter. The flowers, which are bluish-purple and white, are everlasting; and, when out, may be mixed with *Immortelles*. Among other good kinds may be mentioned *S. Hoffordii*, *S. arborea*, *S. brassicaefolia*, *S. imbricata*, and *S. macroptera*, but like *S. profusa* best. Among hardy sorts, which bloom principally in June, July, August, and September, are many with flowers finely diversified in colour, and in height they range from 4 inches to 16 inches. The best for border culture are *S. apiculata* (blue), *S. incana alba* (white), *S. bellidifolia* (rose), *S. auriculata* (red), *S. nana* (blue), and

S. bellidifolia (also blue). The last three are very dwarf, and well adapted for rock-work. All of them bloom profusely and grow freely in common garden soil. The dwarf varieties may be increased in spring by division, and the taller ones by means of cuttings struck in a cold frame. A good type of a hardy Staticeae is here illustrated.

4794. — *Elythrina Crista-galli*. — "T. A. F." asks where this can be obtained, also how to cultivate it? Any good florist or nurseryman will supply it. The "Coral-plant," as this is often called, was introduced from Brazil in 1771, and is quite hardy in well-drained soils if protected from prolonged wet and severe frosts. Ashes or Cocoa-nut-fibre are good to lay over the crowns. Cuttings may be struck similar to Dahlias; but it is more necessary to have a small portion of the old crown attached. When obtained from cuttings plants of a more even height can be secured. It is an excellent plant in a moist greenhouse temperature, and may be treated as follows: When the flowers are over for the autumn, cut them down, and stand

A good hardy Staticeae.

in a pit or cool frame until the end of November, when repot and introduce into gentle heat. This will secure a crop of bloom in March. After this cut them back to within four or five eyes, start in a brisk heat, and thus obtain a second crop of bloom in July or August. This crop may be realised out-of-doors if desired.—P. U.

— This plant was more grown forty years ago than it is now. I remember seeing beds of it in the open air then. In the autumn, when the frost destroyed the flowers, the stems were cut down, the roots lifted and stored away under the greenhouse stage, where they remained dormant all winter. It makes a very useful conservatory plant, but it is still better in the open air. Anyone who can grow and flower a *Fuchsia* or "Gerenium" will do this easily. It is not much grown now, but it may be obtained from any good nursery, especially those having connections with Continental nurseries.—E. H.

— In very favoured spots, such as against a warm wall, and with protection at the roots in winter, this fine plant will live out; but, as a rule, it is a summer flower only, planted out to give beauty to summer bedding. I saw it

very fine this year in Battersea-park, the curious beak-like scarlet flowers having a very quaint aspect. It is much the better plan to lift the plants and keep under cover during the winter. —C. T.

FRUIT.

STORING APPLES.

IT is many years since such an abundant crop of Apples was produced in this country as that now nearly matured, but I am afraid that a great percentage of this useful fruit will be wasted for lack of care in storing for future use, as unfortunately the system of living from hand to month has spread from towns to rural places, and there is little care bestowed on storing, for if anyone advocates the thing they are met with the remark that it does not pay, and that there is sure to be plenty of imported fruit as soon as the home-grown ones are finished, which is doubtless true enough; but certainly home growers are helping the foreigner to get a better price than he ought to get, and home growers are certainly not so often blessed with abundant crops as to be able to neglect to make the most of it when it does come. Early Apples, such as Lord Suffield and others of the Codlin type, are useless for storing, and they must be sold for what they will fetch, which has been a very low price indeed during the past few weeks, but the thing which keeps down the price lower than it really ought to be is the fact that hundreds of bushels of kinds that would be in season at Christmas, and realise a far better price, are gathered and sent to market principally by people who do not appear to know the difference between late and early Apples. Premature gathering is always more or less practised, but this season there is more than usual difficulty in fixing on the right time for gathering, as, owing to the protracted drought, the fruit has fallen from the trees in showers long before the main crop was fit for storing, as, if gathered before they are fully matured, the fruit either shrivels or rots; therefore it is safer to let some fall and use the mass best you can than to risk the whole crop by premature gathering. I have lately seen any quantity of Blenheim Orange, Deux Ans, Wellingtons, and other good keeping Apples in market being sold for about one half what they will be worth at Christmas, and I would strongly urge all who take the trouble to grow good Apples like these to take a little extra pains this year in storing them, for no matter how plentiful or cheap they may be now, depend upon it, the case will be different when the dark days of winter are upon us. As regards the best mode of storing, I do not think that the plan of spreading the fruit out on fruit-room shelves in single layers is either necessary or desirable, for if the fruit is sound and carefully gathered, they may be put together in far less space in barrels or boxes, and keep far better, with very little loss, and my own impression is that late Apples, such as Lane's Prince Albert, require planting more extensively than they have been, for we have such a number of early sorts that if we only grow a tree or two of each, we are almost certain to get overstocked with fruit in September, but any that will keep three months there is little fear of being overdone with them. Old trees, as a rule, are carrying heavy crops this year; but fine samples of clear fruit can only be obtained from healthy young trees, and I would strongly urge all who have trees that produce unsatisfactory crops to grub them up and plant young trees.

JAMES GROOM, Gosport.

A useful Apple.—Apples are plentiful everywhere this year, but never before have I seen trees of any variety so literally "breaking down" with fruit as are those of the Forge, an old and favourite Sussex Apple, in this neighbourhood. There was an abundance of bloom on Apples of all kinds; but this variety seems to have set better than any other, and in most instances the trees are (or rather were, for the crop is for the most part gathered now) loaded with fruit from the base to point of every branch. The fruit is naturally somewhat small, and in the plentiful season, such as this, must be well thinned if handsome specimens are wanted; but both the shape and colour (a deep greenish-

yellow, heavily marked with fine lines of a rich red) leave nothing to be desired. It makes the most delicious tarts and preserves, and when thoroughly ripe is no means to be despised as a dessert fruit, while a noteworthy peculiarity is the very powerful odour exhaled by Apples of this kind when fully ripe. Lastly, the tree is of a neat and compact habit of growth, and seldom misses a fair crop. The trees thrive unusually well on the cold and heavy clay loam that prevails in this district, and when in bloom it is one of the most attractive of all Apples. Unfortunately, most of the fruit here was spoiled by a severe hailstorm on the 8th inst. —B. C. R.

4754.—**Young Vines.**—Pruning or cutting back at once is the true secret of not only the coming season's crop, but also of what is of far greater import—to wit, the foundation of a good Vine, a sturdy, vigorous stem—without which Grapes are only second class. Too often in such cases as noted by the querist, because a Vine has a strong cane or rod it is left. Result—a few strong buds breaking at the upper portion of the rod, while the bottom, if not bare, is too weak to assist the due growth of the Vine. Grapes can be had, and good, from the lower buds, allowing, of course, for the watering not to splash, &c. No doubt, if, say, there are five good eyes a foot from the base of stem, there would be ample. In some cases I have cut down to three; this gives an equal number of laterals each side, and one for the leader. —STEPHEN CASTLE.

4728.—**Compost for Vines.**—“Vineyard,” with his high-sounding cognomen, puts a very pertinent yet important question—in fact, this is the secret of not only the Vine but Grapes growing also. A secret is too often pretended in the preparation of soil, &c. It must be suitable, but not half such a complicated affair as is generally advised. The real compost for Vine-planting cannot be too simple, no manure in any form being required. Any loam approaching to turf, mixed with ordinary road-sidings, with the latter a fair amount of scrapings, can be used. Such mixture, if thrown together for a month, will be all that is wanted for establishing a Vine. Drainage must be good. For ordinary top-dressings a richer material can be used—top-dressings being intended to feed not only the old roots, but also to bring roots nearer the surface. —STEPHEN CASTLE.

4763.—**Grapes not colouring.**—“Anxiano” will not be alone in respect to the faulty colouring of Gros Colmar, the most popular of market or shop Grapes. True, with such a magnificent summer as we have had, with still a fine autumn, all Colmars should be better in this respect than usual. A fair crop for weight, other conditions being favourable, should colour them well. Fire-heat is always a desirable factor—in fact, none of my Gros Colmars are without fire from the time of starting till the Grapes are out. Ventilate always at the top—even a little at night—in front, from daylight till dark, according to the weather, closing entirely in cold or wet nights. A sprinkle of soot on the border inside will be of benefit. Keep foliage intact—the main leaves—but reduce sub-laterals, to give light to the bunches, but not for the sun to shine direct on the fruit. —STEPHEN CASTLE.

4771.—**Grapes for a cold-house.**—Black Alicante cannot be recommended for a cold-house. Certain it is that the fruit will colour—probably better than our universal favourite Hambro—but when it comes to the eating it is disappointing. Fire-heat will bring out the true quality of this, besides making it safe for keeping. Any Grapes grown in cold-houses are most difficult to keep sound any length of time after ripening. Trencham Black on no account must be thought of. Superior as it is for flavour compared with the Hambro, it is far more difficult to grow. Having had this variety in hand for many years I well know its peculiarities. In such a season as the past cold-houses have finished their crop extra well, and the wood is also better ripened, so that the success of the next year's crop is secured. —STEPHEN CASTLE.

4808.—**Treatment of a Fig tree.**—The roots of the Fig tree are too deep. Lift them, and work in some old mortar or builders' rubbish beneath, and lay a few loads of fresh loamy soil on this foundation for the roots to work in. Afterwards, if the growth is thinned in summer,

so as to get the wood ripened, and protection is given in winter, there will be plenty of good Figs. —E. H.

PROFITABLE PEARS.

The season for planting now being at hand, I think it well to call the attention of anyone who may be now entering upon the possession of or management of a garden to look well to the state of the fruit-trees, and I think that Pears claim more attention than has hitherto been given them. I allude especially to their culture on walls. That heavy crop of good fruit are to be met with on standard, pyramid, and bush-trees I readily admit; but these are few and far between, and by far the cleanest and most valuable Pears are to be had from wall-trees. Given shelter and warmth, no matter what the aspect may be, better or more saleable fruit is invariably produced. In years of plenty the best Pears always sell readily, and at good prices, and there is no likelihood of a glut ever occurring. The extensive planting of Pear-trees may, therefore, be safely advised with a view to future profits. At first sight it may appear somewhat useless to recommend planting Pear-trees extensively, especially where the walls are already partially furnished with fruit-trees of various kinds; but I am of opinion that at least one-third of the wall space, including ends of stables, outhouses, and many dwelling-houses, is far from being profitably utilised, and that in very many private gardens room could be found for numerous

Pear "Bourré Bachelier."

young trees. For instance, dessert and cooking Cherries other than Morello rarely, if ever, pay for cultivation against walls, it being possible to buy more fruit with the money saved in netting in one season than can be grown in three years. It would be much better to cut out gradually or otherwise many of the Cherries and replace with Pears. It is also unwise to grow many common Plums against walls that could be turned to a much better account with Pears. That Plums are needed in most establishments there is no denying, but as a rule they do well in the open, and are of far too perishable a nature to be given very much space. I also fail to see why Pears are not quite as ornamental as Wistarias and other strong climbers to be seen against numerous house fronts, and they certainly present a far more tidy appearance than do half-storved Rosas, Lonicera, and such like. Ivy and Virginian Creepers, beautiful as the latter may be at the present time, monopolise far too much wall space, and Pears would grow and cover the walls if not so quickly, yet certainly quite as effectively. Having tried to make out a strong case in favour of Pears, it will not be out of place to further discuss what

VARIETIES might be planted advantageously. Supposing the bulk of the fruit is, when ripe, to be sold, extra regard must be paid to size, colour, and appearance generally, flavour being of secondary importance. In some few instances, however, it is possible to combine a variety of good qualities, and varieties possessing these are to be most commended. Such early sorts as Doyenné d'Été and Citron des Pannes are not worthy of wall space, but if there is a high wall to be covered, Doyenné may be planted. This season Williams' Bon

Chrétien against walls proved very profitable, the standards and bush trees failing to bear any fruit. Space might, therefore, be found for two or three trees of this old favourite. Bourré d'Amanlis very frequently succeeds admirably as a pyramid or standard, but produces finer fruit on wall-trees, and the same may be said of Bourré Superfin. Pitmasdon Duchess also bears well as a pyramid or standard, but the fruit nearly always presents a scratched appearance when ripe, and is not nearly so fine as that obtained from wall-trees. This extra large variety is very profitable, and the quality is not to be despised. Doyenné Boussoche is a sure bearer, and the fruits are extra large and of fine appearance, but, like those of nearly all the preceding, they keep badly. Nouveau Poiteau with me rarely fails, and it is a useful variety, keeping fairly well after it is ripe. Comte de Lamy, though not large, is really a very profitable Pear. It is a heavy cropper, keeps fairly well, and is both attractive in appearance and good in quality. Bourré Clairgean, as far as its quality is concerned, is second-rate, but those who grow for the market ought to plant it, as it is a sure bearer, and the fruits are large, brightly coloured, and ripen early in November. Louise Bonne of Jersey is one of the best for the market, good samples being readily bought up. It is a most reliable variety under any form of training, but the wall-trees produce by far the best fruit. Duchesse d'Angoulême I would also find room for, this being a sure bearer and the fruit large, keeping fairly well. Marie Louise is simply indispensable, and this is one of the most valuable of all Pears. Room ought to be found for several trees of both this and Doyenné du Comice, both being reliable bearers, while good samples of the latter fetch the highest prices in the markets. Bourré Boche-lie (here figured) is a fine serviceable variety, and Huyshé's Prince Consort rarely fails to do well. Bourré Diel proves exceptionally profitable, large old trees seldom failing to bear heavy crops of good-sized fruit, and which, keeping till late in November, generally sell very well. It is the late variety that really pay best, even the Vicar of Winkfield proving more profitable than choice early sorts. Josephine de Malines, Winter Nelis, and Bourré d'Arenberg are somewhat small for market, but they are well worthy of a trial. The latter remark applies to Gerou Morceau (which spelt badly), Olivier de Serree, Bourré Rance, Bergamotte d'Espereu, and Ne Plus Meuris. W.

4792.—**Fruit-trees for a north-east wall.**—I should not like to plant Pears on a wall with this aspect, not that they would not fruit so freely as on any other, but the flavour would be indifferent. Such culinary Plums as Victoria, Magnum Bonum, and Coe's Golden Drop would do very well, and so would Morello Cherries. Such Apples as Lord Suffield and Lord Grosvenor would bear freely in such an aspect, but they would be later in ripening than those on a more sunny aspect. —J. C. C.

I should not plant Pears on a north-east wall. Any Pear that will bear good fruit on such an aspect will do better away from the wall altogether. The difficulty I have found with Pears on a north or north-east aspect is to get flavour, and without flavour Pears are useless. Kitchen Plums and Cherries will do well. Victoria, Pond's Seedling, Goliath, Prince Englebert, the Czar, and White Magnum Bonum. Morello Cherries are always a success, and the May Duke usually does well, and it is an advantage to have a May Duke Cherry-tree on a north wall to come in after those on better aspects. —E. H.

4797.—**Black Currants.**—These enlarged and apparently precocious huds never come to anything, and are, indeed, the work of a very troublesome insect known as Phytomyza ribis. If badly affected the best thing you can do is to cut all the bushes right down to mere stumps at once, and let them make an entirely fresh growth next season. All the branches should be burnt, and the stumps be syringed with a solution of Paris Green. If left alone the disease will ruin the entire plantation. —B. C. R.

4788.—**Pears on a clay soil.**—What are generally known as market Pears, such as Bishop's Thumb, Windsor, and Bourré Giffard, will probably do well on a clay soil; but I should

not like to risk too many. Apples grown in the form of large spreading bushes and grafted on the Crab-stock would be a safer investment. Annie Elizabeth is an Apple that does exceedingly well on a clay soil, and the large and handsome fruit keeps well until the months of May and June.—J. C. C.

The hardest kinds of Pears will succeed on a clay soil; but it will not be wise to plant any of the delicate varieties which are liable to crack and mildew. A good deal depends upon

A hybrid Narcissus.

the climate of the district. I have seen good Pears grown on the Sussex clay, where there was a fair depth of soil over the clay. The land may probably require draining. The Quince usually does well on clay soil, and although I should not plant Pears on the Quince largely anywhere without first trying them, still, it is worth while trying a few trees of some of the hardiest sorts. Hessel or Hazel is a good market Pear, and bears freely on clay soils. Lammas also does well, and usually carries a paying crop. I have known the crop of one tree fetch £5; but the tree was a very large one, and covered a very large space, and was a very handsome object when in bloom. Beurré de Capiaumont, though an inferior Pear, is very free-bearing. Fertility in the same way is a better Pear. Jargonelle in a good climate may succeed, as may also Williams' Bon Chrétien. Among the better class Pears which may be planted in a good climate, are Louise Bonne of Jersey, Marie Louise, Fondante d'Automne, Beurré d'Amanlis, and Pitmaison Duchesse. If the climate is right the soil can be improved. The chief thing to avoid is deep planting. I would rather plant only a few inches deep, and raise a mound of good soil over the roots. Success will depend upon the way in which the planting is done.—E. H.

4814.—**Treatment of Vines.**—When Vines do not bear fruit there must be something very wrong in their management. Probably the roots are out of condition, and if so manure will not help them. Try and find the roots and see what state they are in, and if in a bad condition either lift and make a fresh border for them or else grub them out and plant young Vines. Try and find a good gardener in your neighbourhood to look at them and tell you what is best to be done. No useful remedy can be suggested until their real condition is ascertained. Blood is not a bad manure in moderation for healthy Vines, but the roots of old Vines are often far away from the house in some cold, wet soil, from which they can derive no energy.—E. H.

From the information you send it is very doubtful if your Vines are not too old to be restored to a fruitful condition. If they are not, now is the time to carefully lift the roots and replant them in a new-made border. It is very clear that no sort of manuring will do any good. The case is too bad for that. The roots are in a bad way, and anything short of replacing the Vines with young ones, or lifting the roots and making a new border, will be any use. You had better get someone to advise you who understands Vines, and can see them as they are.—J. C. C.

4813.—**Growing for market.**—A good many are trying to solve the same problem you are at work upon. Some I know are making Tree-Carnations pay, growing only a few kinds. One of the most profitable being Miss Jolie. This, and a good white and good scarlet, will meet all requirements so far as out flowers are

concerned. Winter Cheer will probably make a good winter flower, and La Belle is a good free blooming white—though small, it is very free. Many growers fill up their Tomato-houses with Chrysanthemums, and something can be done with double Zonal "Geraniums," such as F. V. Raspail and others. French Beans will not succeed in so low a temperature, though Mushrooms and Rhubarb and Lettuces might.—E. H.

OUTDOOR PLANTS.

A HYBRID NARCISUS.

AMONG the most graceful and delicate of all Narcissus are the drooping N. triandrus of Spain and Portugal, and the little White Hoop-petticoat of Algeria. These two species can be cross-fertilised without difficulty, and the engraving represents hybrids raised by myself from seed of the Hoop-petticoat fertilised by pollen of N. triandrus. Both Prof. Michael Foster and myself have flowered seedlings the other way of the cross, and the flowers are almost identical with those now shown. G. H. E.

THE BRONZE-LEAF OF JAPAN (RODGERSIA PODOPHYLLA).

THIS splendid plant is really a giant-leaved Saxifrage, and a native of Japan. When well grown in a deep rich border of peat and leaf-mould and duly sheltered from harsh winds, it forms one of the finest of all the exotica plants which are perfectly hardy in our northern climate. Its five great partite leaves each vary from 2 feet to 3 feet in diameter, and are of a rich ruddy bronzy tint with the peculiar rugose or shagreen-leather-like appearance peculiar to the unfolding leaves of the Horse-Chestnut in early spring. Such leaves, borne aloft on cylindrical stalks 2 feet to 3 feet in height, and the plants grouped naturally together as shown in our engraving, have a tropical-like aspect, especially when judiciously planted near to more slender grassy-leaved vegetation for the sake of contrast. The group now figured nestled at the foot of a colony of Bamboos near an old tank or well, and the result was a very happy one. Although grown as, and indeed most remarkable as a foliage plant, yet as seen at their best the plumose spikes of white Spiræa-like flowers are really very beautiful. The plant has long had a history and a name in Japanese gardens, whence it was introduced to the United States by Captain Rodgers of the American Navy, after whom it was named. The native name in Japan is Yagurumaso, and a very characteristic wood-cut of it is given in Vol. VIII., tab. 27, of the celebrated work on the herbaceous plants of Japan, originally written by Pinouma Yokoussai, and republished by the editor, Tanaka Yosiwo, in 1874. This interesting work in twenty volumes contains woodcut figures with Latin names of nearly all the herbaceous perennials and annuals, wild or cultivated, in the gardens of Japan, and is well worth the perusal of those interested in the plants of that country. The illustration is from a photograph kindly sent by Mr. Greenwood Pim. It represents a specimen at least 5 feet in diameter which was growing in Mrs. Lawronson's garden at Sutton, near Howth, Co. Dublin. F. W. B.

4806.—**Convolvulus minor.**—This ought to do well, but no doubt your garden suits the Tropæolums better. Try next year, if you have not already got, the Canary Creeper, T. canariense. It is very beautiful until quite late in the year, and grows freely, smothered with yellow flowers against the light-green leafage. In moist spots and a little shade, the Flame-flower (T. speciosum) might be established, but it is not a town flower, although easily grown in country places. The finest of the tall-growing annual Tropæolums, forms of T. Lobbianum, are of a grey-whitish colour, cardinal, scarlet; Triomphe de Gand, orange-scarlet and brilliant-scarlet, centre crimson. There is no question that Tropæolums are good plants for suburban gardens. They bear smoke and other afflictions better than most

things. I think too little use is made of the climbing kinds, which are quite as attractive and certainly more graceful than the compact little varieties.—C. T.

DWARF FUCHSIAS.

A CORRESPONDENT asks for advice about Fuchsias and the dwarf F. Duurobin Bedder, which I mentioned a few weeks back? The latter, I believe, is not yet in the trade; but it will shortly be, and is well suited for a small garden, or a larger place, where it may be made use of as an edging to a bed filled with taller kinds. As regards hardy Fuchsias, much depends upon the positions in which they are placed as to what height they attain. In seashore districts, where it is warm and sheltered, and in gardens in Wales and Scotland, they attain great luxuriance, and are superb shrubs, smothered with crimson flowers. In less genial climes they reach about 3 feet in height, even less, unless, of course, naturally dwarf, such as F. discolor. One of the most popular of this class is F. Riccartoni, which is also very hardy, seldom getting killed outright, even in the more exposed districts. It will not stand a bleak position. F. pumila and F. microphylla are dwarf, and if they get cut down in winter shoot up again in spring. In unusually severe weather it is advisable to cover the crowns with coal-ashes or similar material as a protection against protracted frost. A familiar kind is F. coccinea, which attains many feet in height in favourable spots. The flowers are crimson, and the leaves get tinged with red. F. conica grows about 3 feet in height in ordinary gardens, but I have seen it higher in the Isle of Wight. It has scarlet and purple flowers; but I should not get it before the others mentioned—at least, F. Riccartoni and F. coccinea. F. corallina, the slender-growing F. gracilis, and F. globosa are all worthy of mention. The last-named is very free in bloom, the flowers of rich colour and borne in profusion. V. C.

SOWING GRASS SEEDS.

THE long protracted drought has been a great trial to the finest lawn Grasses, and where there was much traffic on it, such as occurs on cricket, lawn-tennis, and croquet lawns, there will doubtless be plenty of bare places requiring to be made good, and it is by no means an easy matter to get turf that is free from noxious weeds of some kind or other, and as seed can be got of any kind of Grasses or Clover quite free

Rodgersia podophylla. Engraved from a photograph.

from any admixture, it will if sown at once make a better job of the filling up than any attempt at patching with fresh turf. Now that plenty of rain has fallen to soften the soil, it should have a good scratching with a sharp-toothed rake, then sow the seed, and cover with finely-sifted soil, rolling it down firm when dry on the surface; and to cease the old roots to strike out into vigorous growth a top-dressing of soot and guano should be applied, so as to get a good covering of Grass before winter sets in, as this will keep the frost out of the soil, and do more

to protect the young Grasses than any artificial protection that can be given. It is so usual to sow early in the spring that many neglect the best time for sowing—viz., the autumn, which is really the most natural time, as the seed which has ripened during the heat of summer drops naturally to the earth, and the heavy rains of autumn causes it to spring up vigorously, and get a good hold of the soil. A great deal of mischief is done by worms loosening the young plants at the early stages of growth. But this should be remedied by a frequent use of the roller.

J. G., Gosport.

CHINA ASTERS.

At many autumn exhibitions the China Aster is shown, and in a grotesque way. It holds court with the African Marigold, and both are made ridiculous by the flowers being stuck on boards or cards without a vestige of stalk or leaf. One would scarcely know these very charming flowers in such a disguise—I mean when seen in full character in the garden. The China Aster is not without a certain degree of elegance, and the African Marigold is far from formal, its heavy, rich-coloured flowers being set off by feathery deep-green foliage. The China Aster must not be confounded with the Michaelmas Daisies (the Perennial Asters), as the former are annuals, and very beautiful when well grown. A small garden may be made gay at little cost with these beautiful flowers, which, in the various sections, so to say, display considerable variety of colouring as well as form. The original species, sent from China, had single flowers, but the florist has raised the present race of fine double kinds. The chief men to whom merit belongs being Mr. Betteridge, amongst English florists, and, of the Frenchmen, Truffaut perhaps claims first place, although several other well-known men have worked successfully. The China Aster is a large family, split up into distinct groups, such as the Victoria, Penny-flowered, Dwarf Chrysanthemum, the Rose, the Quilled, and the Emperor. Of this series the Dwarf Chrysanthemum and the Victoria are, by reason of their dwarfer habit of growth, best adapted for bedding. They form neat plants, a perfect mass of bloom in the early autumn, and fill the garden with rich colour. I have a strong liking for the taller kinds, as they are less formal, and it is easier to cut a few blooms for the house if so desired. The Quilled Asters are delightful, but in the small gardens it will not be possible to get every type, so that the selection must be left to individual taste. Few annuals are more readily grown than the China Asters. Even with only the aid of a greenhouse and careful cultivation the plants may be had in bloom in both pots and the open. A few flowering specimens are very welcome for the house or window. The time to sow the seed is about the second week in March. Sow thickly in 5 inch pots, well crocked and filled with a light soil. If possible place in a gentle heat to promote quick germination. At any rate, the greenhouse should not be exposed to frost. When the little plants have made about four leaves, prick them out about 3 inches apart. If to be grown in pots, they must be potted on until they are in 5 inch or 4 1/2 size, and use on a light soil—say, loam mixed with well decayed leaf-mould and manure. Never let them get dry, and keep them as near the glass as possible, otherwise the shoots get much drawn. If required for the open, first prepare the places for them, and the soil must be fairly rich. Unless this is so the flowers are undersized, and last only a brief time in beauty. It pays well to enrich the soil for Asters. Provide good food for the roots to go down into, and therefore give them endurance in times of drought, such as the present year. Asters not planted in a good staple this season have had a sorry time and quickly fallen a prey to insect pests. In such a splendid year as the present for seed-sowing one might save their own seed, although it is not expensive to purchase. Still there is pleasure in growing one's flowers from home-saved seed, reserving a few plants for the purpose. All blooms should be removed from them, except, say, four of the finest, and the seed gathered when ripe. Clean it thoroughly, and place in a small basket: put in a dry place for sowing in the spring. China Asters are much troubled at times with earwigs, which eat the blooms. The best way to keep

the pest is by placing small flower-pots amongst the plants, putting a little Moss into the bottom of each, and each morning shake the Moss over a can of boiling water; the earwigs will fall into the trap readily. Green-fly and other small marauders are also very troublesome, and may be eradicated by watering them overhead at frequent intervals with soft-soap and water, using 1 1/2 oz of soap to 1 gallon of water.

V. C.

THE HARDIEST LILIES.

The flower of the past season has been the Lily, and though sorely tried by the drought, it was very beautiful in the garden, the stems being shorter than usual, owing to the severe drought. We see *Lilium* more often in the large than the small garden, but it is a bulb not very difficult to cultivate, if one selects the more hardy and easily-grown forms. The

GOLDEN-RAYED LILY (*L. auratum*) has been very beautiful, and bulbs of this can be purchased cheaply. It is quite hardy, and succeeds particularly well amongst Rhododendrons. The secret is that the soil is fairly light, and not too moist, whilst the rising shoots get protection in spring from nipping frosts. The flowers of this fine species are of remarkable beauty, large, freely produced, and finely coloured, sometimes almost self-creamy white, or bordered with intense crimson. This variability of colouring is a great charm. It is curious to notice in cultivating Lilies that those bulbs in a somewhat moist and partially shaded position are always more satisfactory than in drier spots, in fact, coolness is what they require. A very hardy and showy old Lily is *L. croceum*, which succeeds as well in London as any other kind. Its flowers are very richly coloured, and the bulbs will grow satisfactorily in pots. One often sees a good specimen in a London forecourt, but it is very few of the Lily tribe that will grow under such conditions. *L. canadense* (the Canadian Lily) is a pleasing flower, and the orange-yellow flowers look well in the border; the plant thrives well in moderately light soil. Everyone is familiar with the pure-white *L. candidum*, which seems to succeed well in the cottage garden and in more pretentious places. It has flowered much better this year than usual, and we have seen less of the peculiarly trying disease which spoils otherwise beautiful breaks. A large mass of it is very charming. The finest lot of it I have ever seen was in a Bath garden. The position was sloping and very sunny. A mass of the pure-white fragrant flowers was presented to the eye—a delightful picture, got with very little trouble and expense. I feel sure that is the successful culture of this bulb is to disturb the clumps as little as possible. Amateurs are too fond of interfering with their Lilies, and it is this interference that works ruin. The Scarlet Martagon Lily is a good species, especially in northern gardens, where the flowers seem to be richer in colour than in more southern places. It will live in quite ordinary gardens, and I have seen it very fine in cottage plots. Then we have the useful Martagon Lilies, of which there are several varieties, ranging from white to purple-violet. A good group of them is pleasing, but their fulsome odour is rather unpleasant. They live in any soil, and are amongst the most easily grown of all Lilies. Very beautiful is the Great American Lily (*Lilium superbum*), which is very tall in growth, the stems rising to a height of 9 feet or 10 feet. It is a good hardy Lily, very graceful, and the flowers vary in colour from brilliant scarlet, some almost orange, and handsomely spotted. The early-flowering Buff Lily (*Lilium testaceum*) is very handsome in a group. Its large buff flowers look well in a bold group. The Tiger Lilies are very effective, and the finest of all is *Lilium tigrinum splendens*, which justifies its name. Its flowers are brilliant crimson, spotted with dark spots. They appear late, and are strikingly handsome. Then one can have the lovely varieties of *L. speciosum* (rosy-crimson) and the white variety, *Kramtzeri*, which has pure-white flowers. They are both easy to grow in a good soil, and in perfection in early autumn. *L. avenaceum* is a pleasing Japanese kind, the flowers orange-red in colour and spotted.

C. T.

cheapest and most familiar is *F. Riccartoni*, which will stand ordinary winters, but when severe should have some kind of protection to the roots. It is very charming often in southern seaside gardens, but I have seen it near London very fine, even at Finchley, which is considered a very cold district. I remember well a hedge of it leading up to a baker's shop, and throughout each summer the graceful twigs were loaded with the pendent crimson flowers. Another good kind is *F. oocinea*, which makes a very fine bush, and likes a well-drained soil, a remark that applies to hardy Fuchsias in general. *F. discolor* is a very hardy kind, and will live out well in the more northern districts of England, even in Scotland. It is dwarfier than the others. *F. globosa* and *F. gracillaris* are both very beautiful, but if you only require one kind, our choice would be *F. Riccartoni*.—C. T.

4780.—Herbaceous plants and rabbits.—It is useless to set out anything but the strongest-growing plants where rabbits abound, not that they always eat them, but they scratch them out of the ground as soon as they are planted. I used to have a large breadth of Solomon's Seal that they never disturbed. The Flag Iris (*Iris germanica*) is another plant that when well established is too strong rooted for them to interfere with, as are also the different varieties of *Tritomas*. *Diosma Fraxinella* is not rabbit-proof, but I have known them to pass it over in search of food. *Campanula pyramidalis* appears to be distasteful to these creatures, as I have had it for many years in a border overrun by them. In the way of flowering shrubs there is nothing better than the two forms of *Hydrangea paniculata* and *Hortensia*. For large borders the following Grasses are useful: *Eulalia japonica* variegata, *Arundo canapicula*, and the Pampas.—J. C. C.

4800.—Fence behind border.—Your proposal is quite practicable, but the amount of success you obtain will depend a good deal on the class of Roses and Clematis you select. If it is much exposed only the most hardy Roses should be planted, such as the Dundee Rambler, *Félicité Perpetuelle*, *Gloire de Dijon*, and *Sir J. Paxton*. If the position is fairly well sheltered, such strong growing Hybrid Perpetuals as *Climbing Victor Verdier*, *C. Bessie Johnson*, and *Madame Gabriel Linzet* will thrive. Still stronger growers will be found in *Aimée Vibert*, *Rive d'Or*, and *Cheshunt Hybrid*. The best Clematis will be *Jackman* and *Prince of Wales*. The top of the fence may have a fringe of *Clematis montana*.—J. C. C.

4804.—Seedling Anemones.—These Anemones are quite hardy, and succeed better in a bed or border in the open air than under glass. It is their natural habit to flower in the winter when the weather is open. A mulch of leaf-mould or light manure is all the protection required.—E. H.

Leaves on lawns.—As this is the season of the year when leaves are so troublesome on lawns, &c., a very good broom for sweeping them into rows, when they can be easily gathered, is made by taking an old wooden rake, knock out the teeth, and cut to leave six spaces between the holes; then get some young Birch branches, and bind on with strong twine, passing the twine through the holes left by the teeth, and bind the Birch firmly on. This makes a light and very useful broom, as the long handle enables the sweeper to clear a wide space.—ARTHUR ELSON.

4812.—A garden at Leyton.—As far as I remember, the soil in this district is light. Roses will not do much good, but you may try a *Gloire de Dijon* and an *Aimée Vibert* or two. *Chrysanthemum*, *Michaelmas Daisies*, *Hollyhocks*, *Harpalium*, *Doronicums*, *Delphiniums*, *Eschscholias*, *Carnations*, *Pinks*, *Campanulas* of sorts, *Veronicas*, and a few others will thrive. Lilies of several kinds will do fairly well in good soil.—B. C. R.

4807.—Using manure.—A mulch of manure on the borders of full of perennials will be very beneficial, and as such borders usually contain bulbs and other plants which are now dormant, the mulch of manure will shelter and afford nutriment during the time roots are forming, and in the spring, when the dormant plants appear above ground, fork the manure in; but it will be better not to use the spade.—

Hardy Fuchsias.—There are a number of beautiful hardy Fuchsias and

E. H. OF ILLINOIS AT

HOUSE & WINDOW GARDENING.

CUT FLOWERS IN THE HOUSE.

It is in bouquets I have noticed more errors, I think, than in any other kind of floral arrangements. Take, for instance, that well known and justly appreciated flower, the Lapageria, of which, as a rule, the white variety is more used in bouquets than the red kind. In nearly every instance the blooms used are arranged upright, or nearly so, totally out of all character with the natural beauty and elegance of the flower, the best part of which is hidden by other things. If anyone saw it thus and had never seen it in a growing condition he would not be able to form any conception of its real beauty. Why, now, may I ask, should not this flower be allowed to droop down in a natural way upon the outer margin? It would there be in much better keeping. Fuchsias used to be arranged in a similar fashion, but I have not seen them so much of late years. If these elegant flowers cannot be employed in a natural manner, better not use them at all. Of late years some people, the florists in particular, have taken to spooling the Rose by redrawing the petals, transposing what should be a bud in the beauty of its unfolding into what might be taken without any stretch of imagination for a Camellia. I and others no doubt have seen the practice carried too far, especially when cut Roses are thus operated upon to a serious extent. The Eucharis when growing is rarely seen erect, yet it is used often as the centre flower for a bouquet; whereas it would look far better if placed upon the side in a semi-erect manner. That well known Gladiolus The Bride when need in a cut state is sometimes seen the wrong way upwards, the beauty of the interior of the flowers being in a manner lost. I have seen Dendrobium blooms used in bouquets and vases the wrong way about, the flowers thus, to say the least, looking rather singular. Another flower which I have seen totally misrepresented is Kalosanthus coocinea, great pains being taken first to pull the tubes to pieces and then mount each single pip upon a wire. If anyone first saw it thus and afterwards purchased a plant, he might possibly imagine he had an improved kind. Other instances might be quoted, but the above are sufficient to show the absurdity of the methods which some adopt, thinking thereby to add to the beauty of their arrangements, whereas quite the opposite is the case. In all kinds of decorations with cut flowers I maintain that the natural growth should, as far as possible, be adhered to. An excellent arrangement of Madonna Lilies and White Gladioli is shown in the accompanying illustration.

CHINESE PRIMULAS FOR A WINDOW.

THERE are few better flowering plants for room decoration than the Chinese Primulas; and there is now such a wide range of colour, from purest white to deep-red, pink, and even blue, being also represented, that they are without exception the winter flower for a window. They do well in the dry air of a room, and continue to throw up their neat sprays of blossom for months, if well attended to, the only difficulty

being removed to the window & worm sitting-room. Potted as seedlings into thumb-pots, the smallest size, they will require one or two shifts as they grow, never overpotting them, however, for they do best without this, and are apt to damp off if surrounded by a mass of soil in a pot. The best soil for them is a compost of two parts turfy loam to one of leaf-mould, with a little soot and sand, the soot being only in the proportion of one twentieth of the whole. Good drainage, covered with a bit of Moss to keep it

OUR READERS' ILLUSTRATIONS: Madonna Lilies and White Gladioli. Engraved for GARDENING ILLUSTRATED from a photograph sent by Miss Armstrong, Clifton-terrace, Monkstown, Dublin.

clear, is essential, for they must not be allowed to want for water, yet they cannot endure stagnant water about their roots. The little plants must not be allowed to waste their strength in premature blooming. All buds made before they are taken in should be nipped off, and unless the plants are of a good size it will be best to sacrifice the first spray of blossom after September rather than exhaust the plant.

PLANTS which thus store up their flowering powers will continue to bloom without intermission in a sunny window throughout the winter, and are not as likely to die off prematurely as those which throw up small end early blossoms often do. Water must be given in sufficient quantities to run through the pot whenever the surface-soil is dry, but not otherwise, for soaking a damp plant is a fruitful source of evil. Cut and dried roses as to watering every day, twice a week, &c., are a mistake. All plants in pots should be looked over every morning to see whether they need watering, but each one should have separate attention, as their needs vary with their growth, the size of the pot, the weather, and the atmosphere in which they are, so that hard-and-fast rules are quite inappropriate here.

PRIMULAS are apt to rot off just at the collar—i.e., the part of the plant which issues from the soil, and it is dangerous to pour water, especially if it be cold, on this delicate point. Lukewarm water is best for all room plants, and, if possible, it should be rain-water, the saucers being emptied half an hour after the water is given. Another danger which many room plants are subject to is their treatment during the necessary morning turn-out of the sitting-room. Windows and doors wide

being cast, which makes them rapidly drop their flowers. Those who wish to grow them extensively should now sow the seed for next season, autumn sown plants being far finer than those which have only the summer in which to grow, and coming earlier to bloom. But where a few good plants only are needed, it is best to procure them as seedlings, when it is easy to select double or single varieties of any special tint. These can now be put into small pots and grown on in the open air, standing, if possible, in a bed of ashes until the weather becomes frosty in September, when they should

open on the coldest winter morning, dust flying round them from the carpet, and sometimes a hasty push into a corner which breaks their leaves, are some of the dangers which are by no means easy to guard against. Perhaps the best solution of these difficulties is to cover the plants before leaving the room at night with shelters made of cap-wire and paper of a suitable size, placing them all together, if necessary, on a side-table, where they are not to be disturbed. These covers are very easy to make, with one or two circles of the wire, strengthened by a few side stays (according to the size needed), double

newspapers being pasted over the whole, and a wire handle arranged at the top. They not only protect the plants from dust and draughts at night, but also from the danger of a frosty night, and might be much more constantly used than they are for window plants, many of which are left every winter in an unaccountable way for want of some such shelter. They cost but a few pence, and any handy person can easily construct them. They are also quickly renewed if the paper should become broken or soiled. The only alternative to ensure safety for room plants is to move them into a warm bedroom at night, where they should stand until the necessary domestic arrangements are over in the sitting-room, being placed at a distance from the window during cold weather. L. R.

TUBEROSES FOR A ROOM.

The elegant form and rich, tropical scent of these flowers make them specially desirable for room decoration, and many who have but little fire-heat at command may grow them with care, so as to have them in bloom during the latter part of the summer. Bulbs of the Excelior Pearl (American) variety are preferable to those from Africa, as they are not so tall in habit and produce more flowers. These bulbs should be planted as soon as procured—one in each 6-inch pot—the compost used being a mixture of turfy-loam, three parts to one of leaf-mould, with a sprinkling of soot and enough sand to make the compost light. Good drainage is essential, the crooks being covered with a bit of dry Moss to keep the way open for water, for the special danger of the bulbs is that they may rot before they start into life. Having potted them just below the surface of the soil in this compost, which should be neither in a very wet nor very dry state, they will require no water for about a month, and then should have enough to run through the pot, and no more for another week or two. They must, in fact, be kept very dry, though not dust-dry, until the green shoots appear at the top, which will not be until the spring, the time varying according to the amount of heat to which they are subjected. If no heated greenhouse be available a kitchen-window will suit them during the winter, and, indeed, this is an excellent place, if sunny, for them until they are in bloom, for they need all the warmth they can get when once in good growth. Water must then be supplied regularly and liberally, as they grow rapidly when they begin to throw up their flowering-spikes, and should then be given liquid-manure or soot-water in a very thin, clear state once or twice a week. During the past hot summer Tuberoses placed in the open air in pots have done well, and thrown up their exquisite flowers. In the writer's garden, although placed out-of-doors to retard them (others being kept under glass), these plants flowered but little later than those in the conservatory. It is thus evident that Tuberoses can be grown well without a greenhouse, for nothing could have exceeded the sturdy beauty of these outside plants, their exquisite fragrance being also in full force when their waxen petals opened. The bulbs were wintered in ainery just kept above freezing-point, and had no fire-heat whatever after the beginning of April. The blooms opened towards the end of August, and were then of much value for drawing-room decoration after those which had been kept under glass had finished flowering. J. L.

VIOLETS FOR A WINDOW.

Those who wish to have these deliciously-scented flowers in their rooms should now procure some well-cultivated clumps of the variety Marie Louise, which is the most satisfactory of Violets, although the Blue Neapolitan, the soft grey Parma Violet, and the fine White Swanley Giant (Comte de Brazza) are also all worth growing. These clumps should be either potted without much disturbance of the soil or placed in well-drained boxes (a window-box being very suitable) and allowed to remain outside in the open air until the first frosts appear. The Violets named above, being all double, will require shelter during severe weather, but at the same time they must not be exposed to much fire-heat, and will do best in the window of a room without a fire. Where needed for decoration, they are best grown in pots which

can be brought into the drawing-room for the afternoon, and replaced at night in cool air, either in a cool greenhouse or an unused room. Fire-heat has the effect on these plants of inducing a fresh growth of leaves. Where this takes place no more flowers are produced, and the plants, although looking fresh and healthy, refuse to open their buds in a most provoking way. The best place of all for Violets is in a cool frame, raised so as to be only just under the glass, so that they can be sheltered in frosty weather and given all the air possible during a milder time. They may also be grown in a glass porch without heat, especially if the morning

Large-rooted Chicory.

sun shines on it. If grown in a window they must have plenty of air daily, except in extreme cold, and be placed as near the glass as possible; an east or south-east aspect will suit them better than the west, and the soil should be kept damp with a resed pot. Violets grow best in leaf-mould with a little old hot-bed stuff and some good loam mixed with it, sand, soot, and lime being added in small quantities, old mortar rubbish being the best form in which to give the necessary admixture of lime. L. R.

LILIUM HARRISI (THE BERMUDA LILY) FOR A WINDOW.

This pure-white trumpet-shaped Lily is specially suited for room decoration, as it blooms so early in the year, and will bear more warmth than most other Lilies. Bulbs procured now and potted at once often give two sets of blossoms, one opening in April or May, and the second stems (appearing directly the first flowers have faded) grow rapidly even out-of-doors without difficulty. The potting of Lily-bulbs is, however, quite distinct from that of other plants, and to do it rightly it is necessary to understand that Lilies have two separate sets of roots—i.e., the fleshy, tuberous roots which start from the base of the bulb (and which should be disturbed as little as possible), and the fibrous surface roots which grow from the stem of the Lily as it rises out of the ground. In order to allow for these valuable surface-roots, on the strength of which much of the size and beauty of the flower depends, Lily-bulbs should be planted low down in the soil, and repeated top-dressings be added as the Lily grows. Having drained the pot carefully (which should be about 8 inches across for a large Lily-bulb), the rougher part of the soil should be laid over the drainage, with a sprinkling of soot, to exclude worms and insects. The best soil for Lilies is turfy mould (i.e., the turfs out from an old pasture, and stacked in a dry place until the roots of the Grass are dead) with leaf-mould, and a little soot and sand. If manure be added (except as a top-dressing, later on) it must be very old, as anything like fermentation is likely to canker and destroy the bulb. Having placed a small heap of compost over the drainage, the bulb should be planted on it, with a sprinkling of silver sand, on which it should rest, spreading out the thick lower roots towards the edge of the pot, and filling the pot two-thirds full of depth with good soil, which should not be too

tightly rammed down, but only made moderately firm, or the bulb, when the roots increase, may push its way up out of the soil for want of room. The compost used should be mixed beforehand, and wetted until it is of a regular dampness throughout, neither very wet nor too dry; and this is an important point, as the bulb after planting must not be watered for some weeks. The soil in which it is planted should, however, be maintained at about the same dampness by placing the pot in a bed of ashes (or a box of ashes on the leads of a town house will do), covering it completely with damp ashes to the depth of 2 inches or 3 inches, and the surrounding ashes must be kept damp by an occasional watering on the surface, though heavy rain should be excluded by a piece of board laid over the pots containing the bulbs. Before root sets in the plant should be taken into the greenhouse or window, the ashes cleared away, and a top-dressing of rich light soil placed over the surface, leaving room for a second top-dressing of soil later on, which may be of old manure and a little soot. The Bermuda Lily, thus treated and regularly watered after growth commences, should do well if given plenty of air and sunshine in a window. Green-fly will, however, give trouble by attacking the coiled-up leaves, unless measures be taken to prevent this. The best way to destroy this blight is to dip the heads of the Lily in a mixture of Quassia chips and soft-soap boiled together. A teacupful of Quassia chips, placed in a saucepan with a quart of water, should boil for ten minutes, when 2 oz. of soft-soap can be added to it, and the mixture removed from the fire as soon as this is dissolved by stirring. Three quarts of cold water added to this will make the whole quantity 2 gallons, and this will prove a useful bath for any window-plants which may be infested with green-fly, using it to dip them in two or three times a week, until all traces of the pest has disappeared. A bit of soft sponge with clear water should be used to keep the foliage clean from dust, and sharp draughts—especially those caused by the needful brushing of the sitting-room each morning—must be carefully guarded against. I. L. R.

THE KITCHEN GARDEN.

LARGE-ROOTED CHICORY.

In reply to several queries, this is a variety of the common Chicory, and although but little grown in this country, it is cultivated on an extensive scale in some parts of France for the sake of the roots, from which is manufactured the Chicory-of-commerce. It is also grown by some of the Parisian market gardeners, as the blanched tops which it produces in winter are of rather finer appearance than those obtained from the typical form. I would advise these who make a practice of forcing Chicory to give the large-rooted variety a trial. It requires the same general treatment as the ordinary kind, but when thinned out should have more space for development. It is best to sow the seed in rows 1 foot apart, allowing a space of from 6 inches to 8 inches (according to the character of the soil) from plant to plant. Do not sow before May, or the plants will run to seed. Give them an open position and cleanly culture, and large, well-matured roots will be obtained; these, if placed during winter in a warm, dark place, will furnish an abundance of crisp blanched leaves, which will be found a very acceptable addition to the usual run of winter salads. B.

4799.—Best kinds of Rhubarb.—I may briefly mention that the best of all Rhubarbs for pie-making is Hawke's Champagne, which is very different to the thick, flavourless, big-stalked kinds grown in market gardens. Hawke's Champagne is a very slender kind, the shoots deep-crimson right through, and full of juice. This is really delicious, and may be especially recommended for small gardens, or where good flavour counts for more than mere size.—C. T.

—Grow the Paragon for early use, and the Victoria for main crop; the latter also forces well, but will not, of course, come so early as an early kind. Early Linnæus forces well, and comes early outside.—E. H.

4795.—Superphosphate and Potatoes.—It does not depend on the kind, and after a

good many years experience I regard a good sample of superphosphate as decidedly the best artificial manure for this crop, under ordinary circumstances. I always use it, and even on a stiff clay soil, not at all naturally suitable for this crop, I grow as fine, clean, and handsome tubers as anyone could desire.—B. C. R.

I have seen this used very largely for Potatoes, but never knew a case of scab arising therefrom, and I think on most soils it may be used with advantage.—E. H.

4798.—Seed Potatoes.—This is an entire fallacy. A set of most careful experiments made this summer by a gentleman interested in horticulture have given as a result a net loss in the crop obtained from steeped seed of nearly twelve bushels per acre as against the produce of unsteeped seed, the loss, moreover, being chiefly in the larger or "ware" Potatoes. The seed (Champions) was steeped in a solution of half-a-pound of sulphate of Ammonia and half-a-pound of nitrate of potash to each gallon of water, and left in the liquid for twenty-four hours, then dried and planted. I must add that for my own part I cannot see in what possible way such treatment is likely to prove beneficial to the crop.—B. C. R.

4796.—Green Tomatoes.—You have only to cut the fruit (preferably in bunches) and place it on a shelf or in a drawer in any warm place, such as a kitchen, and sooner or later all that are anything like full-grown will ripen, or at least become coloured, and though the later ones lack substance and quality, they come in nicely for flavouring and making sauce, &c. The small green ones may be made into an excellent pickle, and for this several recipes have been given in GARDENING from time to time.—B. C. R.

If they have attained to unable state they will ripen in any warm place. They might be gathered and placed in the kitchen on the shelves, or cut, with a portion of stem attached, and hung up wherever there is warmth.—E. H.

Gather them as ones, and place them in a sunny window, or on the ledge of a warm-house to ripen. I believe a very good preservative can be made from them, but have never tried it. Perhaps some other reader can oblige you in this respect. If the fruits are not too small they will ripen up well in a sunny window, or on a shelf near the glass.—C. T.

4901.—Celery.—Was the Celery watered after being earthed up? From some cause or other moisture has penetrated the heart, and produced decay. Possibly the earth has been built up too high.—E. H.

4745.—Moving Asparagus.—This is not the best time to move Asparagus, if one had any choice in the matter. Still, it may be moved safely now. Take up as carefully as possible without injuring the roots, and replant again as soon as convenient, so that the roots receive no check. Mulch over the bed with manure as soon as planted.—E. H.

4815.—Basic slag.—The value of basic slag as a manure lies in the amount of phosphoric acid it contains, hence it is of use only as a substitute for superphosphate of lime (or bone-meal). It is, however, decidedly cheaper than either of these substances, and though not quite so prompt in action as superphosphate, is much more so than bone-meal. It is especially suitable as a dressing for meadows, light sandy soils, old meadows, clay lands, or, indeed, for any formation that is naturally deficient in lime as well as requiring phosphoric acid. It is also an excellent fertiliser for Potatoes, and, indeed, for root crops of all kinds, and may be employed at the rate of from 3 cwt. to 5 cwt. per acre. There are a good many different makes or "brands" of basic slag in the market, some of which are comparatively useless. That known as Thomas' Phosphate Powder is one of the best.—B. C. R.

4729.—The Bride Gladiolus.—Put at once in any good soil that will grow "Geraniums" and Fuchsias well. Put six bulbs in a 5-inch pot, and nine bulbs in a 6-inch pot, cover about half an inch, and plunge in a cold frame for a few weeks. In forcing they will not bear a strong heat. If brought on in a warm greenhouse, where the temperature is about 50 deg. at night they will bloom about Easter.—E. H.

No time should be lost in potting the corms, five in a 4½-inch pot in a compost of two parts shry-loam, one of leaf-mould, with sufficient sharp silver sand to keep the whole porous, adding a small quantity of dissolved bones if the loam is poor in quality—say, half a pint of manure to one peck of the compost. Stand the pots on a shelf in a cool-house or frame secure from frost. If the soil is moist but little water will be required until growth commences.—S. P.

CHRYSANTHEMUMS.

NOTES ON CHRYSANTHEMUMS.

THE SEASON.—The Chrysanthemum season is likely to be finer than last year, and the displays in the various public parks are quite up to the average. It must be a poor park now that does not have an annual Chrysanthemum exhibition, the Government parks being, I believe, exceptions. The weather has been fairly favourable for keeping the blooms fresh, and no serious complaints are heard of damping. It is necessary to keep a little heat, or to maintain a buoyant atmosphere, and give the plants as much space as possible. From what I have seen, the old varieties are very popular still—I mean such kinds as Elaine and the finely-coloured Source d'Or. If only two kinds were required for early bloom these would be still difficult to beat for all-round excellence.

Mlle. Therese Rey.—Amateurs who exhibit Chrysanthemums should make note of this fine variety. It is really very beautiful, and the best raised for many years. As yet it is scarcely known at all, but will appear in some stands at the exhibitions now being held throughout the length and breadth of England. The flowers are large—but then no variety stands a chance now for exhibition unless it is broad and massive—creamy-white, and graceful, so to say, in expression. It is neither coarse nor ungainly, and one I admire greatly, although adverse to big flowers as a rule.

Vivian Morel.—This variety is of a remarkably sportive character. Chas. Davis, a bronze-coloured kind, is a sport from it, and likely to be much grown. The pure-white flower is got from an early hand, the later buds producing blooms of the warm rose-purple colour, which is accepted as the proper character of this variable kind. I saw the white and the lilac-purple on the same plant recently, but in spite of this quixotic nature this variety is a really splendid Chrysanthemum.

Crimson Coloured Varieties.—There is quite a long list of deep-crimson purple-coloured kinds, such as William Gerard and John Shrimpton. The flowers are large, but refined, and the shade of colour is of super depth, with

an suffusion. An unnamed seedling I saw is a fair advance on Meg Merrilies, a variety that is superseded now, this novelty being fuller. The flowers of this are of a milky-white colour, and with the petals out, so to speak. Amos Perry (yellow) and Excelior are good additions, especially the last mentioned, which is a flower of remarkable size, rose-purple, the petals curling inwards and showing the silvery reverse. The greatest sensation, so to say, this year will be Mme. Therese Rey, described above.

CHRYSANTHEMUM COTTAGE PINK.—Passing through a Kentish village the other day I saw a fine mass of this variety coming into bloom. It should be introduced into suburban gardens, the flowers, rosy-purple in colour, freely produced, and they throw off rains better than any other outdoor kind known to me. It is very similar to a very old variety called Emperor of China, and is very free, hardy, and thrives in fine or bad weather through November, lasting sometimes into December. I saw it in full bloom in a southern seaside garden last year at Christmastime. The Anemone-flowered Chrysanthemums (see illustration) are very pretty and well worthy of extended culture. V. C.

TREES & SHRUBS

ROCK ROSES (CISTUSES).

SUCH fine shrubs as the Cistuses were, when badgers held complete sway, lost to our gardens, and many good forms disappeared. This delightful group is entitled to a good place; the shrubs are not troublesome to grow, have a wealth of glossy leafage, and in the case of such kinds as C. ladaniferus or the Gum Cistus bear flowers of much beauty. It has been urged that they are not hardy, but C. ladaniferus and others will live out even in Scotland. This is a proof of the hardihood of the Cistuses, but some are more tender than others, and only those that live out-of-doors will receive mention here. I like to see them massed together, and a bed of C. laurifolius maculatus or one of the other types is a pleasant feature during the summer months, when the shrubs are in flower. I have seen in the south of England dry sunny banks clothed with them, banks upon which very few other things would succeed. One of the most useful is the Gum Cistus (C. ladaniferus), which has long been in English gardens, as it was grown as early as 1656, by Tradescant jun. Its flowering season extends during the three summer months, from June to August, when it gives beauty to English gardens as well as the Spanish wilds from whence it was introduced. The species has white flowers, but there is a variety named maculatus in which the white ground is relieved at the base of each of the petals by a blotch of rich purple. When in a suitable position the shrub will grow about 5 feet or 6 feet high, and when brushed against gives off a sweet, balsamic fragrance, due to a gummy secretion in the summer months. This rich perfume is very strong, and a bed of shrubs can be detected some distance away, although unseen; the leaves are shining as if polished, narrow, and abundant, giving a bushy character to the plant. Another very beautiful species is C. laurifolius, which has also been long in cultivation, and is indispensable in every good garden. It is hardy, and delightful when in full bloom, as the flowers are borne freely, and create a pleasing effect against the smooth, polished leafage, which is also comparatively broad. Its chief charm is the profusion of flowers; but even finer than the type is the variety maculatus. Its flowering is usually confined to June and July, and, like C. ladaniferus, comes from Spain; but it is long since it was introduced, as in 1752 it was cultivated by the celebrated Miller. These two types are the first to commence with, and are the hardiest; but several others may be grown, these being of dwarfier growth, as C. monspeliensis, C. creticus, C. orisopus, C. lusitanicus, C. hircutus, not forgetting also C. purpureus. One great advantage of the grouping system, apart from the better effect the several plants have, is that in the event of exceptionally severe weather protection may be given, this taking the form of mats hooped over them. This will not be necessary, however, except in weather of great severity, when it is often necessary to protect plants and shrubs considered perfectly hardy. Every care

Anemone-flowered Chrysanthemum.

an old-gold reverse to the florets. The habit of growth is dwarf, or comparatively so, and one good thing is this dwarfing of the growth. Plants six or seven feet high are no advantage. I prefer the neater and more compact specimens.

NEW JAPANESE KINDS.—There is a wealth of new and beautiful Japanese varieties, and several novelties which I have seen privately will be shown in the course of the autumn. Col. M. B. Swete is already known, and it is a very fine flower, very large, with only a trace of coarseness and the colour is bronze-yellow, with a

should be taken of the *Cistuses*. They re- pay for trouble and a proper knowledge of their requirements. One of the chief things necessary is dryness. A damp air, such as is frequently experienced in low lying situations, especially in the winter, inflicts greater harm than frost; and in the neighbourhood of London the foul yellow fogs are a severe trial to the shrubs. The position for them should be in the first place dry, and, if possible, well exposed. Under these conditions the plants will bloom freely, and the foliage, if they are near large towns, keeps freer from sooty deposits. If the garden is very confined, then Rock Roses are not likely to succeed, as I have watched their behaviour in recent years, and always find that they thrive best where the soil is dry and the situation exposed, so there is little damp. Like the beautiful little Sun Rose that love to scramble over a dry bank, gilding it into colour, the *Cistuses* also prefer a dry soil, poor, uninviting, and apparently not capable of supporting plant life. But here they flourish and enjoy the material in which the roots have found entrance. There are many dry, bare banks in gardens, on which nothing but coarse weeds thrive, that may be converted into a picture of leaf and flower by planting upon them the Rock Roses. Throughout their cultivation there is little trouble with them, as they are easily propagated by seeds, which ripen well and germinate readily, or by cuttings. The cuttings will soon strike if taken in September, the earlier the better, inserted in pots filled with an ordinary light soil, and transferred to a cold frame. They soon make headway if, when struck, they are potted off singly in the usual way. In the spring they may be planted out. V. C.

4892.—*Clomelia Flammula*.—Are you certain the kind is this? But in some years flowers lose their fragrance to some extent, a good deal depending upon the weather. I have often noticed this—a very fragrant flower under certain conditions almost losing its characteristic scent. This is the only explanation, I should think, that could be afforded.—C. T.

I can only suggest that the want of fragrance in your *Clematis* was caused by the hot, dry weather that prevailed at the time it was in flower. Many flowers suffered in the past summer from the same cause. Carnations especially; the sweetness in these could only be detected in some varieties early in the morning or late in the day. J. C. C.

The Siberian Crab—Few trees are more suitable for a small lawn than *Pyrus malus haccata* (the Siberian Crab), which is charming when in flower, but still more so through the autumn and winter, when lit up with its profusion of crimson fruits. But even if it neither flowered nor produced such a wealth of handsome fruits, the Siberian Crab would be of note for the extreme gracefulness of its growth. It is always a pleasure to see a good specimen, and as it does not attain a very large size, it is suitable for comparatively small lawns. The tree is, of course, perfectly hardy, and not fastidious, requiring no special soil or position. As the planting season is near at hand, it should not be overlooked. One sees so many poor things in gardens, "Monkey Pizzas," half-dead, and a surfeit of variegated Maples, that the Siberian Crab should be planted if only for the sake of variety.—V. C.

A good Rhododendron ("Heleno-Schiffer")—This is a new kind, and doubtless is expensive; but in time it is one of those plants that will be popular because of its usefulness and beauty. It was raised, I believe, on the Continent, from whence we have got many such things, as they are made more of there than in England. It is a delightful pot-plant, and was exhibited at the summer show of the Royal Botanic Society. The plant is of very compact habit, which fits it for the smaller greenhouses, in which it is impossible to grow the larger habit kinds. The flowers are white, and produced in neat trusses. When offered for sale it should be made note of.—V. C.

The Pearl Bush (*Eucryphia planatifolia*, not *E. pinnatifida*, as it is sometimes called) is a shrub that all who live in the northern districts of England should take note of. The flowers are large, pure white, not unlike those of the St. John's Wort, and with a bunch of yellow stamens in the centre, which seems to intensify the purity of the segments. A large bush in full bloom in summer is very charming, the flowers set off by an abundance of foliage of polished green colour. It was introduced from Chili, and no shelter need be given to the

bushes, which in more than one southern garden have been established there for several years. In its native country it grows about 10 feet in height, and in the flowering season is covered with blossom. It will thrive in ordinary soil, provided that it is well drained, and the position should not be too exposed, otherwise a succession of severe frosts is likely to prove destructive. But it is worth a little protection in all the more northern districts, its distinct character and lovely flowers well repaying for any attention of this kind.—C. T.

ORCHIDS

ODONTOGLOSSUM BICTONENSE.

THIS is an Orchid which formerly used to be grown with a great deal of pleasure, and a very nice display it yielded in those days when fewer plants could be found to make a show of blossom during the dull season of the year. Even now it should not be cast on one side because it has a special interest, as being the very first *Odontoglossum* which flowered in English gardens, and this was in the year 1836, having been sent from Guatemala by its discoverer, Mr. Skinner, who, in speaking of this plant as he found it, stated it "is quite destitute of a rhizome. It has oblong pseudo-bulbs with narrow leaves. It is always terrestrial, half buried in mossy banks." Thus "G. M. II" may see what the finder of this species says of it as it grows in its native home. "G. M. H." sends me a spike of this plant for a name, asking at the same time if it is the typical form of the plant? To this inquiry I should say no, it is not the usual variety we see in English gardens, but it much resembles a form which I have seen flowering in the houses in German gardens under the name of *speciosum*. It is near to the variety called *splendens* with us, but it has a much duller lip, and the flower is smaller. The specific name is derived from its first flowering at Bicton, then in the possession of Lord Rolle, but numerous varieties have appeared since that time, the most distinct, if not the most handsome, being the form called *album*, which has the sepals and petals of a deep brown, and the cordate lip of a pure white. Another form called *splendens* is a very robust kind, and it produces a dense many-flowered raceme, with large blossoms in which the sepals and petals are of a rich brown, transversely streaked with greenish-yellow, the large cordate lip being of a lively rosy-lilac; sulphureous, sepals and petals pale yellow, with a white lip. All these varieties I have seen at Mr. Bull's establishment, where the species is thought a great deal of, and done well. It has been found in Mexico, as well as in Guatemala, and under cultivation it likes a somewhat warmer situation than do such plants as *C. Pescatorei* and *O. orisipum*, and upon this account I have no doubt was due the fact of its succeeding so much better than many things which succumbed to their fate; but I have always found it to be a plant very easy to grow, but at the same time to like a little water to help it through the winter, instead of being quite dry. MATT. BRAMBLE.

CYPRIPEDIUM SPICERIANUM.

I AM in receipt of four flowers of this kind from "M. J.," and, as he says, they all represent a different form slightly. No. 1 I take to be the normal and typical one. No. 2 is a small flower, with very narrow petals, and it is very dull coloured, certainly one of the very poorest I have seen of the species for a long time, and I should cast this one out from the collection, he it ever so small. No. 3 is a very pretty flower, with a large dorsal sepal, and with short, undulated petals; it is most distinct and beautiful, and should be well looked after. No. 4 is a fine and beautiful flower, having a large dorsal sepal, with a very broad central streak of purple colour, the whole of a pure white, tinged with flesh colour, the base green. These varieties, coming from seed in their native country, show what a marked change can be effected in the kind. Some of my friends tell me they have read that *Cypripedium* are not increased in this way, because they do not produce seed, and that they are a set of plants that are fast becoming extinct. But yet our collectors still find new kinds. Mr. Sander has reaped quite a harvest from the new varieties he is constantly having sent home to

him of the mentanum type of *C. insignis*, and amongst them stands the chaste and lovely *C. insignis Sanderæ*. Then, again, more recently we have the beautiful *C. Charlesworthi*, introduced by the Messrs. Charlesworth and Shuttleworth, of Bradford. Then, again, to go back only a short time, we have the *C. Chamberlaini*, introduced by Mr. Sander, which, although it does not produce more than one flower at a time on a scape, yet a plant with several growths may have as many spikes, and thus its lovely flowers are increased. Then, again, another distinct and evergreen kind is the *C. Sandarionum*, and the equally fine and free-flowering *C. Rothschildianum*, and the beautiful *C. Curtisii*, which, however, was first introduced by the Messrs. Veitch, *C. bellatulum* by the Messrs. Low, of Clapton, and many other fine forms, which seem to show us that the longer we search, the finer and more exquisite forms we find, so that if they are a dying-out race they are determined to excel in beautiful forms to the end of the chapter. But I must now return to the *C. Spicerianum*. This was first seen in flower in this country some fifteen years ago. This passed into the hands of Messrs. Veitch, and it remained a rare plant for several years, but at length its habitat was found out by the Messrs. Low's collectors, and soon after by those sent out by Mr. Sander. It has been a wonderful favourite in our collections ever since, and it has become a favourite Orchid with our numerous hybridizers, and some excellent forms have resulted from it, of which I may note *O. Leeanum*, *C. Figure*, *C. Hera*, *C. Buchenianum*, *C. Hornianum*, *C. Lathamianum*, *C. Niebe*, and many others, which have all had *C. Spicerianum* for one of their parents. This plant comes from Assam, or from some part of Northern India, which has not been divulged by the collectors, but it thrives well with other species and hybrids of the same genus, potted in the same way, adding a little loam to the peat and Sphagnum Moss. They last in bloom for a very long time, but when their flowers are past I like to keep them in the *Odontoglossum*-house for the resting season, removing them to the warmer house in the spring to make their growth. MATT. BRAMBLE.

CATTLEYA BOWRINGIANA.

IT is now less than ten years ago that Messrs. Veitch introduced this plant from Central America, and from time to time I have recommended readers of *GARDENING* to invest in it, for it is a splendid thing. This *Cattleya* flowers at this season and right through the month of November in great beauty; and at no time of the year should it be kept either dry at the root or without moisture in the air. We are not told at what altitude it grows in its native country, which is British Honduras; but it is found beside the rivers, so that it is enabled to gather a great deal of moisture in the dry season from evaporation, whilst in the wet season the rainfall is very great, so that it will not answer to let the plants get dry at any one time in the year, or they will then get badly infested with thrips; so much have I seen this plant smothered in these insects as to be of a greyish-black. But this was entirely owing to their being in a quite dry house with no moisture in the air; and the plants were dry, too, at the roots, and from which they never recovered. MATT. BRAMBLE.

4816.—**Fixing hot-water pipes.**—If the connections leading to the eastern were free, as they should be, there could be no more pressure in the pipes than that produced by the head of water—a few feet only; but the pipe may have become blocked in some way. You do not say of what material the joints are composed. I prefer Portland cement to anything else, and like it more the longer I use it. If the cement is fresh and properly worked in, the joints will never leak a drop, and last almost a lifetime. The fact of the lower or return pipe having a greater inclination than the flow is of no consequence; the flow ought to have a rise of at least 1 inch in every yard, though rather more is perhaps better; but with a good rise from the boiler into pipes the inch is enough. A 2-inch connection is large enough for anything up to about 200 feet of 3-inch piping; but where there is a long length of any size to heat, it is better

to have the gauge the same throughout. I suppose you mean you cannot keep the 3 inch pipe tight on the 2 inch nozzle on the boiler? By making a Portland cement joint you can easily do so. I often run a 2 inch (or even 1-inch) pipe into the socket of a 4-inch, and with plenty of fresh cement, and a few hits of broken brick, can make a joint in ten minutes that will never lose a drop of water. I will tell you how to make the cement joints, if you like; three hours after finishing them you can fill up the pipes and light the fire.—B. C. R.

FERNS.

FILMY FERNS FOR WARDIAN CASES.

"T. J. M." writes me that he should like to know which of the New Zealand kinds he can accommodate in a north-east window? Well, you may grow all or any of these in a case so situated, and it will become one of the most beautiful ornaments for a room that can be conceived. "T. J. M." sends me a list of the kinds he has coming home by a mail steamer, which, if they should arrive in anything like condition, will soon thrive apace. Now I have seen many styles of Wardian cases for Ferns, but I think the most effective was one fitted with a shallow zinc tray, in which small and large pieces of sandstone rock were stood up and arranged in a picturesque manner, and upon this was placed in the first instance a small pot with Filmy Ferns. These had climbed upon the blocks of sandstone, so as to quite cover them with verdure, the kidney-shaped kind from New Zealand being quite conspicuous, not only for its shape, but for the beautiful bright greenery of its fronds. This plant is frequently called a rare New Zealand kind, but it is not so, for a gentleman, who lives next door to me now, has just returned from a twenty-five years' residence in New Zealand, and he tells me it is a species which is plentiful in its habitat, and from the great quantities of this plants which I saw when at Kew last in the celebrated Cooper Foster collection, it should not either be considered a rare plant in this country; but it does keep a rare plant in England, which is a great pity. I have specimens with fertile fronds gathered in New Zealand, but I have never but once seen a frond which had been grown in this country with its row of fertile cups round the edge of the fronds. Some of the kinds mentioned by "T. J. M." have short and stout rhizomes, which will not creep and fix themselves upon the block of sandstone, and for these a suitable place or places for their accommodation should be provided near the base of these. Such kinds as *Trichomanes elongatum*, *T. striatum*, *Hymenophyllum seahrum*, and the two *Todeas* may all be taken as examples, and for the *Todea superba* ample space should be allowed for this to spread and develop itself, when it will become one of the most beautiful objects in the whole case. Although not, strictly speaking, a Filmy Fern, *Hymenophyllum dilatatum* is a fine, broad-fronded, stately species which requires ample space, so also does *H. seahrum* and *H. demissum*. The other kinds are smaller growing, and they have creeping rhizomes. The *Trichomanes elongatum* also makes fronds nearly 1 foot in height, as also does *T. striatum*, and should be provided for accordingly. These plants should be potted in small, well-drained pots, the soil being composed of equal parts of loam, peat, and Sphagnum Moss. These should be placed in the permanent places they are to occupy, then the zinc tray should be filled with water, the surface covered with pieces of wirework, and the whole covered with growing Sphagnum Moss, which will require cutting back a bit, as it grows too strong, and with an occasional dusting with the syringe nothing more is necessary. J. J.

Parley Fern.—Referring to the remarks on Parley Fern (*Allosorus crispus*) in GARDENING of October 21, I may say that this Fern grows well in our garden—a cold, exposed, but high situation. We have some fine plants brought fourteen years ago from North Wales, others from Westmorland and Cumberland brought more recently; but all are in a flourishing, healthy condition. They seem to do well in a tolerably shady place facing north and north-east. I give them no special soil, but wedge them tightly between the stones which

support a steep bank. The soil is light gravel. They bear both sterile and fertile fronds abundantly, but so far as I have noticed they have produced no seedlings, although the *Leutrea Filix-mas* and *Filix-femina* seed freely in the same bank.—A. S. SOUTHWALL.

INDOOR PLANTS.

MARGUERITES.

THE varieties of *Chrysanthemum frutescens*, which are popularly known as Paris Daisies or Marguerites, have now been grown for a considerable time, and are recognised as belonging to the most popular of market plants; yet when they were first grown for market it was generally anticipated that they would have a very short run. Anyone not acquainted with Covent-garden Flower Market would be astonished at the immense quantities to be seen there throughout the spring months. It is chiefly the white varieties that are grown; the yellow forms are equally if not more desirable, but they are not so easily managed. It is not only for pots that the Marguerites are useful, as they are equally valuable as bedding plants, and for window-boxes there are few things that will keep up a good display of bloom so long. For winter flowering or early flowering, plants propagated late the previous spring are best. These may be out back about midsummer, and after they have well started again they may be

but this, though it flowers well early in the spring, does not keep up a succession of bloom as well as *Halleri maximum*. Of yellow varieties *Etoile d'Or* is the best known, but it is a little difficult to manage. Cut-back plants do not break freely, and even young plants when stopped do not branch out regularly. *Feu d'Or* is a free-growing variety which may be recommended, the flowers being similar to those of *Etoile d'Or*. It must not be treated too liberally, or the plants will be apt to run up tall. *Comte de Chambord* is sometimes met with, but it is not a very desirable variety, the flowers being pale-yellow and smaller than those of the above. Its only recommendation is that it is of a dwarfier and more branching habit. F.

CYCADS, AND WHAT I KNOW OF THEM.

I THINK this somewhat a pertinent question from an unknown friend from Liverpool, signing himself "Kaffir." In his letter he says, "Tell me through GARDENING what you know about Cycade, and if they may be grown in an ordinary greenhouse?" Well, I may tell you at once that they cannot be grown in an ordinary house set apart for greenhouse plants, because this would be too moist for them during the winter. It is true I have observed that Mr. Wm. Bull, of Chelsea, maintains a lot of these plants in his large conservatory with other plants through the winter months, and they appear to do well, but the kinds that I have

Flowers of Marguerite (*Chrysanthemum frutescens*).

potted on into 5-inch pots. They may require stopping once or twice, but where four or five sheets start evenly together they will make good plants, as they branch out naturally when they begin to flower. For flowering later in the spring autumn-struck plants are best. These should now be ready for potting into 5-inch pots. They may require stopping once or twice, and the tops will be useful for cuttings, which will make good plants in time for bedding out. There is very little difficulty in the culture of Marguerites, as the cuttings will root freely on a hot-bed. If there should be a scarcity of good cuttings, a few old plants may be cut back, and these will soon break out and give a good supply. Marguerites may be potted in any ordinary garden soil; rich compost should be avoided, or the plants will make too much growth. After the plants are well set with bloom they may be fed with liquid-mannure. One great drawback to their culture is that they are much subject to a small maggot, which is difficult to deal with on account of its being under the surface of the leaves. The only means of keeping this enemy in check is by using paraffin as an insecticide. There are several distinct white varieties, but they are not now often seen under names. That which I have seen named *Halleri maximum* is the best; the flowers are large and the habit of the plant good. *Pinnatifidum*, a small-flowered variety, with very pretty, finely-cut leaves of a pale glaucous green, used to be grown a good deal, but I have not seen much of it lately. There is also a good large-flowered variety with pale-green, rather finely-cut leaves of dwarf habit,

mostly observed there are South African and Australian species and varieties. The kinds from the East Indies and those kinds from Central America and the West Indian Islands are not represented, and therefore I say to grow a good representative collection of these plants one requires a slightly warmer and drier house than the ordinary structure which is devoted to ordinary flowering and fine foliaged plants from cool countries, whilst in the spring and early summer months they revel in a good supply of heat and moisture also. This is the time when they usually make their growth, but sometimes a season may roll past with no new growth being developed, and when this is the case, the plants should be kept quiet and dryish, as it is of no use to try to force growth upon them. These plants have been said to have cylindrical undivided stems, and in this respect much resemble Palms, but anyone who visits the Amsterdam Botanic Garden will here find that this description must be read with a little caution. In this place there was a very fine collection. I suppose this came about through the Dutch having early access to South Africa, and finding the species somewhat plentiful they secured a good supply; but here, at Amsterdam, may be seen several of the fine Cape species, having branched stems, as well as the Chinese *Cycas revoluta*, having several branches, and one plant of the East Indian *C. circinalis* here had three branches upon it. I have seen one or two other examples of this species with a branched stem, but it would appear to be only the male plant

which branches in this kind; what the others may do I cannot tell. These plants are peculiarly suitable for the amateur's greenhouse, because they do not quickly grow out of bounds, so that they excol in their beauty and their lasting qualities, for the house which is large enough for them will be equally roomy come ten or twenty years hence, so that here they differ from Tree-Ferns and Palms. These get too tall in twenty years for the house, and have to be done away with, but with Cycads the process of stem building is effected but by slow degrees. Many new kinds have been discovered in Australia during the last thirty years, but the most remarkable plant was sent home in 1862, which differs from every other species of the order, and it goes to prove that Australia is the oldest hit of the world known, for here Mr. Hill found the *Boweria spectabilis*, having a stem some 60 feet high, and with bipinnate leaves, and this form is only known to exist in our coal measures. The plant was first found in the early part of the century, during Flinders' voyage, but when it appeared in the vignette of the book of the history of the voyage it was simply considered to be a fancy of the artist, as no one could believe in such a plant. I have seen many species of the order in the numerous gardens I have visited during my sojourn through Europe, but I have never seen so much attention paid to their culture as in Leipzig; but it is in Saxony that the fashion prevails of using the leaves of *Cycas revoluta* as memorials of the dead, and of late years I have seen one place only in England where a speciality is made of the same species. This was at the Albert Nurseries, Pookham-rye, which is conducted by Mr. C. Hicks. Here a large house is devoted to them, and highly decorative they look, so that we may be led to see what a highly decorative plant it is, with its deep-green leaves, which resemble the feathers of the ostrich in outline. The fossil remains of this order are found in various part of our own country and other parts of Europe, but all have long since disappeared from these once-familiar places, and they now appear in the greatest numbers at the Cape of Good Hope and neighbourhood and in the land of the Antipodes. A few scattered species are found through the East India and the Indian Islands, several come from South America, Mexico, and the West Indian Islands, but the majority of those natives of the Western Hemisphere have slender stems and are quicker growers. The first plant of *Eucopalarctos Caffol*, which is also called the Kafir's Bread-tree, was introduced to this country in 1775. It was living a few years ago, and could have been accommodated after all these years in any amateur's greenhouse standing only 4 feet in height. I would earnestly recommend "Kafir" to go in for these plants strongly, as they will not overgrow the height for many years. These plants may be potted in good turfy loam and sharp silver sand, and the pots should be well drained. Give an abundance of water through the summer months, but a very little through the winter; yet I do not like to treat them as dry blocks, just a little moisture being necessary to maintain the leaves in good and healthy condition. I think this is all that I know about Cycads that may be useful to "Kafir." I have not entered upon the economic properties; but these he may find out by studying the order. Neither have I done anything in the way of describing the species, for there is a great resemblance in the general run of the plants. Of course, there are some striking deviations. I think there are altogether less than a hundred species of the order known, principally confined to the under-named genera: *Boweria*, *Catakidozamia*, *Ceratozamia*, *Cycas*, *Dion*, *Eocopalarctes*, *Lepidozamia*, *Macrozamia*, *Stangeria*, *Zamia*.

TUBEROSES.

FEW flowers are more valued in autumn and winter than the Tuberoses. Especially is this so where there is a large and constant demand for such as are useful in button-hole work. Tuberoses, it must be admitted, are suited to this class of work, and alike useful are they in wreaths, crosses, or bouquets. It is now possible to have them in bloom almost all the year round, and though, of course, in common with all flowers, they open very slowly in the early of winter, yet it is satisfactory to know that a

fair percentage of their flowers expand tolerably well. The very latest batches should now be in the open and throwing up their flower-spikes in various stages. To secure these from accident, a stick should be placed to each, with a loose tie to admit of future growth, and if the pots are stood closely together, little harm should result. At this time also keep them free of the side growths that form about the bulbs to the detriment of the flowering stem and flowers. Give the plants abundant supplies of water at the root and weak liquid-manne every other day. Syringe freely and regularly so as to check as much as possible the progress of red-spider, thrips and the like, which are almost sure to infest them. An occasional watering overhead with clear soft-water will also conduce to the same end. Beat of all, perhaps, is an occasional

SPRINKLING WITH QUASSIA-CHIPS and soft soap. Take a 6-inch potful of the Quassia-chips and place in an old saucopan with soft water, and boil steadily till the whole of the chips have sunk to the bottom; then drain it off and add a large teaspoonful of soft-soap, stirring well till dissolved, adding sufficient cold soft water to make two gallons of the whole, but if not sufficient, increase the proportion of chips and soap till enough has been made to give a good syringing all round. In using the syringe for this purpose the jet is always preferable to the rose, because with the former a steady spray is maintained, and all sides of the plants can be reached. It is a mistake to dash quantities of these insecticides against the plants, because the great hulk goes to the soil and is lost; whereas with the jet a mere mist-like spray is the result, and has the effect of just damping the leaves and stems. A spraying of this kind may be repeated frequently and at a very trifling cost, and gardeners generally should not lose sight of this cheap and effectual remedy. In the case of Tuberoses persevere with it while the plants are yet outside and the insects less numerous. When the plants are housed the drier atmosphere conduces to their rapid increase, when they frequently get the upper hand. By this time the whole of the plants constituting this batch should be secure in pits and frames away from the reach of frost, a few degrees of which will prove fatal to them in this stage. Provide abundance of air on all favourable occasions, and daily while the plants are in frames at closing time give them a nice sprinkling overhead with a fine rose. This will also tend to keep insect enemies in check. From time to time the most forward may be introduced into warmth as required, and with care a supply of flowers may be kept up till the end of the year.

POTTING EARLY BULBS.

It very often happens that we do not remember to do this in time to secure the most satisfactory results. If a compost of leaf-soil, loam, and the thoroughly decayed portion of an old Cucumber or Melon-bed be used, together with good drainage, almost all bulbs will do well. It materially assists them, however, to have a dash of sharp sand placed around their base at the time of potting. No bulbs do so well if placed into heat immediately as when they are stood in a pit or frame for a short time previous to being removed to the greenhouse. The roots need to be well at work before the tops are excited. The size of pot must depend upon the sort of bulb. The following will do well if from seven to nine bulbs be placed in a 5-inch pot: *Freesias*, *Ixias*, *Sparaxis*, *Jonquils*, *Narcissus bobacodium*, *Allium neapolitanum*, and *Soilles*, also *Grape Hyacinths*, and *Lachenalia's*. Roman *Hyacinths*, *Tulips*, *Leucojoms*, *Zephyranthes*, *Narcissus*, *Hyacinthus candicans*, *Fritillarias*, and the smaller *Hyacinths* have most effect when placed three to five in a 5-inch pot. Large bulbs of *Hyacinths*, also the various *Liliums*, will do better if potted into the same size singly. A well-matured bulb does not need much space, as the bulk of the true is practically stored up in the bulb. All of them should be grown steadily, especially during the earliest stages, and they will require a good supply of water as soon as the soil is permeated with roots.

P. U.

449.—Keeping Fuchsias through winter.—These Fuchsias may possibly survive

in a collar, but it greatly depends upon the atmosphere there, as they will probably mildew unless there is a circulation of air. Fuchsias are so nearly hardy that they can be kept in any out-house, or in a spare room, with safety, if they are well hardened out-of-doors in autumn, and kept very dry at the roots. They would do much better and flower earlier if kept in the light and air, but if this is impossible the cellar might be tried. Laying pot-plants "on their side," is usually done to prevent drip-water from eoddening them in winter; there would be no object in doing this, probably, in the cellar, and the plants would be more likely to live if they were allowed to keep their natural perpendicular. In any case they should be hardened as much as possible, and kept in the open air until severe frost threatens them, then dried thoroughly before they are placed in the lightest and most airy part of the cellar.—I. L. R.

BEDDING "GERANIUMS."

THE long protracted drought caused bedding "Geraniums" to flower profusely, but with far less leaf-growth than usual; consequently, many owners of gardens have found it difficult to provide the requisite number of cuttings; but, as a rule, there are far less losses among cuttings in such a season as this than there are in wet, sunless seasons, as the growth is firm and well matured, and the "Geranium" will stand any amount of drying when in the cutting state, but very little wet without rotting; but as a safeguard it will be well to take care of as many old plants now as possible, and to do this they should be lifted before any frost has affected them, and pot them up singly or also put them thickly in boxes, working fine light soil among the roots, and giving one good soaking of water to settle the soil down firm, and then keep moderately dry. I pick off all the large leaves, only leaving the small ones on the tips of the shoots. They do very well in any pits or frames until the end of November, when they must be put on shelves near the glass in any light house where a little warmth can be applied, more with the object of dispelling damp than of raising the temperature, as it is not advisable to excite growth before the days begin to lengthen. Keep them just moist enough to prevent the leaves flagging, and as soon as the sun begins to shine in spring give more water and they will rapidly develop into fine plants, and supply plenty of cuttings.

J. G. Hunt.

4791.—Plants for a vinery and greenhouse.—The *Chrysothemum* is one of the best plants to grow for flowers during the autumn and winter, and they can be kept in the vinery whilst in bloom, also afterwards; in fact, this is the usual place for them in many gardens. Then you could have in the greenhouse, provided it is heated, *Zonal Pelargoniums*, *Fuchsias*, *Chinese Primulas*, *Persian Cyclamens*, *Ferns*, *Myrtles*, *Tuberous Begonias*, *Daffodils*, and other hardy bulbs in pots, small *Camellias* and *Azaleas*, and as creepers the *Lagereria* (crimson and white), *Plumbago capensis*, *Tree Carnations*, *Heaths*, especially *Erias hyemalis*, *Cinarrarias*, a variety of hard-wooded things, and *Salvias*. But much depends upon what artificial manure can be given, the position of the house, and the amount of time you can devote to the plants.—C. T.

—*Chrysothemum* will do very well in the vinery after most of the Grapes are out, and as they make most of their growth outside, they only require shelter to perfect their flowers. *Mignonette*, *Primulas*, *Calceolarias*, *Cyclamens*, and *Zonal "Geraniums"* are easily grown, and will succeed well with just a little warmth in winter; but only the hardiest kinds of *Zonals* should be included, as, for the most part, to do them well they require more heat than will be good for the Vines. For summer grow *Tuberous Begonias* and *Fuchsias*, both of which may be placed outside when the Grapes require more attention. Many other plants may be, and, in fact, are, grown under Vines, but the above are easily managed.—E. H.

4793.—A leaky roof.—The only alternative in entirely stripping and replacing the roof is to carefully scrape away all the loose putty, both inside and out, and rake out any faults between the glass and bars. Then carefully fill up all the spaces with fresh putty, pressing

it well in end smoothing off neatly. Lastly, paint the bars one or two coats, both inside and out, letting the side of the brush or "tool" just catch the edge of the glass all along the sides. If properly done there will be no drip subsequently, but the whole must be quite dry at the time, or neither putty nor paint will tick.—B. C. R.

4790.—Greenhouse plants.—It depends upon what classes you intend to compost in. Your question is very indefinite. I presume you are an amateur, and if so could not do better than select a Zonal Pelargonium, either double or single variety, or a Fuchsia.—C. T.

—A Tuberosa Begonia and a Zonal or Ivy-leaved Pelargonium, or a Fuchsia, would be very suitable. If you want something more uncommon, a blue Plumbago and a nice white, yellow, or crimson Abutilon might be better.—B. C. R.

4817.—A hot-water boiler.—I cannot make out from your description what kind of a boiler you have got. The only "Star" boiler I know is an independent cylindrical (upright) one. Is yours a kind of saddle or a conical boiler (cast-iron)? Write again, giving a rather more lucid description of the boiler, and I will tell you how to set it. I am very glad to hear the coil works so well.—B. C. R.

—From your description of the arrangement of the pipes they are lowest at the far end, or else on a dead level. Engineers make good work if they get a 1-inch rise in a length of 9-feet pipe. You had better ascertain whether the top pipe is too low, and alter it by raising both the top end bottom pipes, and if it is a small hose the rise should be 3 inches from the boiler to the far end. With regard to your next question a 2-inch pipe fixed on the boiler nose would not hinder the circulation, seeing that it leads into a 3-inch. You are not likely to get the 3-inch pipe to fit securely on the nose of the boiler that is only 2 inches in diameter, unless you make the joint with iron cement. The proper plan, however, is to have what is known as a diminishing piece 2 inches diameter at one end, and 3 inches the other, there will be no difficulty then in the fitting. You do not say what material you used to make the joints with; it was evidently bad, or else the joints were indifferently made. By ramming home first some stout cord so as to fill up about an inch of the space, and filling the remainder with Portland cement, a perfectly strong job can be made. With suitable pipes the india-rubber rings make the best of all joints.—J. C. C.

4805.—An unheated greenhouse.—Three inches will be too near to the glass to train Roses. The frost will not hurt the shoots probably, but there is not room enough to develop either flowers or foliage properly. Give them 6 inches, and although that is rather too cramped, still they may do. Roses in pots may be grown beneath, provided the plants on the roof are kept moderately thin of growth.—E. H.

—The frost in winter is not likely to injure your Roses that are so near the glass. It is in the spring of the year, when the young shoots are sure to touch the glass, that they will suffer, and if they are not killed the leaves are sure to get disfigured. Six inches between the glass and the wires is not near enough. Fourteen inches is not too many. The nearer the Roses are to the glass the more they suffer from the attacks of insects and mildew, because it is more difficult to apply any remedies.—J. C. C.

4790.—Lobelia erinus.—To preserve a good strain of the above they must either be propagated from cuttings or division of the roots. Seedlings do not come so good. Towards the end of September out off the top of a few plants, then lift them as soon as new growth commences. You will find that they can be pulled apart so as to leave some roots upon each piece. These, if potted up or dibbled in round a pan, will make nice clumps next spring. Should you not have enough plants each of these may be further divided in the same manner, except that in the spring there is no need to cut them down previous to parting. This is a very simple and sure plan, all that is necessary to keep them through the winter being a cool greenhouse temperature.—P. U.

—The best place to keep Lobelias through the winter is on a shelf near the glass in a moderately warm greenhouse, which is freely ventilated on every favourable opportunity. Damp is the thing to avoid. If you have a lodge in the centre of the plant they die. Young plants which were divided last August keep the best.—E. H.

RULES FOR CORRESPONDENTS.

Questions.—Queries and answers are inserted in GARDENING free of charge if correspondents follow the rules here laid down for their guidance. All communications for insertion should be clearly and concisely written on one side of the paper only, and addressed to the Editors of GARDENING, 37 Southampton-street, Covent-garden, London. Letters on business should be sent to the Publishers. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Unanswered queries should be repeated. Correspondents should bear in mind that, as GARDENING has to be sent to press some time in advance of date, they cannot always be replied to in the issue immediately following the receipt of their communication.

Answers (which, with the exception of such as cannot well be classified, will be found in their different departments) should always bear the number and title placed against the query replied to, and our readers will greatly oblige us by advising, as far as their knowledge and observations permit, the correspondents who seek assistance. Conditions, soils, and means vary so infinitely that several answers to the same question may often be very useful, and those who reply would do well to mention the localities in which their experience is gained. Correspondents who refer to articles inserted in GARDENING should mention the number in which they appear.

4820.—Tortoise in a garden.—Will a tortoise live during the winter in a garden, and what should it be fed with?—B. D.

4830.—Poplar hedge.—Would someone kindly tell me whether it is now time to prune a Poplar hedge, which has been neglected?—W. E. H.
